As such examples demonstrate, we are social animals. We may assume the best or the worst in others. We may approach them with closed fists or open arms. As the novelist Herman Melville remarked, “We cannot live for ourselves alone. Our lives are connected by a thousand invisible threads.” *Social psychologists* explore these connections by scientifically studying how we *think about, influence, and relate to* one another.

Social Thinking

13-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

Personality psychologists focus on the person. They study the personal traits and dynamics that explain why *different people* may act differently *in a given situation*, such as the one Willems faced. (Would you have helped the jailer out of the icy water?)

Social psychologists focus on the situation. They study the social influences that explain why *the same person* will act differently in *different situations*. Might the jailer have acted differently—opting not to march Willems back to jail—under differing circumstances?

An etching of Dirk Willems by Dutch artist Jan Luyken (from *The Martyrs Mirror*, 1685)

The Fundamental Attribution Error

Our social behavior arises from our social cognition. Especially when the unexpected occurs, we want to understand and explain why people act as they do. After studying how people explain others' behavior, Fritz Heider (1958) proposed an **attribution theory**: We can attribute the behavior to the person's stable, enduring traits (a *dispositional attribution*), or we can attribute it to the situation (a *situational attribution*).

For example, in class, we notice that Juliette seldom talks. Over coffee, Jack talks nonstop. That must be the sort of people they are, we decide. Juliette must be shy and Jack outgoing. Such attributions—to their dispositions—can be valid, because people do have enduring personality traits. But sometimes we fall prey to the **fundamental attribution error** (Ross, 1977): We overestimate the influence of personality and underestimate the influence of situations. In class, Jack may be as quiet as Juliette. Catch Juliette at a party and you may hardly recognize your quiet classmate.

David Napolitan and George Goethals (1979) demonstrated the fundamental attribution error in an experiment with Williams College students. They had students talk, one at a time, with a young woman who acted either cold and critical or warm and friendly. Before the conversations, the researchers told half the students that the woman's behavior would be spontaneous. They told the other half the truth—that they had instructed her to *act* friendly (or unfriendly).

Did hearing the truth affect students' impressions of the woman? Not at all! If the woman acted friendly, both groups decided she really was a warm person. If she acted unfriendly, both decided she really was a cold person. They attributed her behavior to her personal disposition *even when told that her behavior was situational*—that she was merely acting that way for the purposes of the experiment.

What Factors Affect Our Attributions?

The fundamental attribution error appears more often in some cultures than in others. Individualist Westerners more often attribute behavior to people's personal traits. People in East Asian cultures are somewhat more sensitive to the power of the situation (Heine & Ruby, 2010; Kitayama et al., 2009). This difference has appeared in experiments that asked people to view scenes, such as a big fish swimming. Americans focused more on the individual fish, and Japanese people more on the whole scene (Chua et al., 2005; Nisbett, 2003).

We all commit the fundamental attribution error. Consider: Is your psychology instructor shy or outgoing?

If you answer “outgoing,” remember that you know your instructor from one situation—the classroom, which demands outgoing behavior. Your instructor (who

social psychology the scientific study of how we think about, influence, and relate to one another.

attribution theory the theory that we explain someone's behavior by crediting either the situation or the person's disposition.

fundamental attribution error the tendency for observers, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition.

observes his or her own behavior not only in the classroom, but also with family, in meetings, when traveling) might say, “Me, outgoing? It all depends on the situation. In class or with good friends, yes, I’m outgoing. But at professional meetings I’m really rather shy.” Outside their assigned roles, professors seem less professorial, presidents less presidential, managers less managerial.

When we explain *our own* behavior, we are sensitive to how behavior changes with the situation (Idson & Mischel, 2001). (An important exception: We more often attribute our intentional and admirable actions not to situations but to our own good reasons [Malle, 2006; Malle et al., 2007].) We also are sensitive to the power of the situation when we explain the behavior of people we know well and have seen in different contexts. We more often commit the fundamental attribution error when a stranger acts badly. Having only seen that red-faced fan screaming at the referee in the heat of competition, we may assume he is a bad person. But outside the stadium, he may be a good neighbor and a great parent.

As we act, our eyes look outward; we see others’ faces, not our own. If we could take an observer’s point of view, would we become more aware of our own personal style? To test this idea, researchers have filmed two people interacting with a camera behind each person. Then they showed each person a replay of their interaction—filmed from the other person’s perspective. It worked. Seeing their behavior from the other person’s perspective, participants better appreciated the power of the situation (Lassiter & Irvine, 1986; Storms, 1973).

What Are the Consequences of Our Attributions?

The way we explain others’ actions, attributing them to the person or the situation, can have important real-life effects (Fincham & Bradbury, 1993; Fletcher et al., 1990). A person must decide whether to attribute another’s friendliness to romantic or sexual interest. A partner must decide whether a loved one’s tart-tongued remark reflects a bad day or a mean disposition. A jury must decide whether a shooting was malicious or in self-defense. In one study, 181 state judges gave lighter sentences to a violent offender who a scientist testified had a gene that altered brain areas related to aggressiveness (Aspinwall et al., 2012).

Finally, consider the social and economic effects of attribution. How do we explain poverty or unemployment? In Britain, India, Australia, and the United States (Furnham, 1982; Pandey et al., 1982; Wagstaff, 1982; Zucker & Weiner, 1993), political conservatives have tended to place the blame on the personal dispositions of the poor and unemployed: “People generally get what they deserve. Those who don’t work are freeloaders. Those who take initiative can still get ahead.” After inviting people to reflect on the power of choice—by having them recall their own choices or take note of another’s choices—people become more likely to think that people get what they deserve (Savani & Rattan, 2012). Political liberals, and those not primed to consider the power of choice, are more likely to blame past and present situations: “If you or I had to live with the same poor education, lack of opportunity, and discrimination, would we be any better off?” To understand and prevent terrorism, they say, consider the situations that breed terrorists. Better to drain the swamps than swat the mosquitoes.

The point to remember: Our attributions—to a person’s disposition or to the situation—have real consequences.

Some 7 in 10 college women report having experienced a man misattributing her friendliness as a sexual come-on (Jacques-Tiura et al., 2007).

“Otis, shout at that man to pull himself together.”

An attribution question

Whether we attribute poverty and homelessness to social circumstances or to personal dispositions affects and reflects our political views.

 **LaunchPad** For a quick interactive tutorial, visit LaunchPad's *Concept Practice: Making Attributions*.

Attitudes and Actions

13-2 How do attitudes and actions interact?

Attitudes are feelings, often influenced by our beliefs, that predispose our reactions to objects, people, and events. If we *believe* someone is threatening us, we may *feel* fear and anger toward the person and *act* defensively. The traffic between our attitudes and our actions is two-way. Our attitudes affect our actions. And our actions affect our attitudes.

Attitudes Affect Actions

Consider the climate-change debate. On one side are climate-change activists and the Intergovernmental Panel on Climate Change (2014), which warn of accumulating greenhouse gases, melting glaciers, shrinking Arctic ice, rising seas, dying coral reefs, migrating species and vegetation, and extreme and warming weather. On the other side are climate-change skeptics, who include many in the general public. The 31 percent who in 1998 thought “the seriousness of global warming is generally exaggerated” increased to 42 percent in 2014 (Dugan, 2014). And the 34 percent of Americans who in 2014 told Gallup they worry “a great deal” about global warming was essentially the same as in 1989 (Newport, 2014).

Knowing that public attitudes affect public policies, activists on both sides are aiming to persuade. Persuasion efforts generally take two forms:

- **Peripheral route persuasion** doesn't engage systematic thinking, but does produce fast results as people respond to uninformative cues (such as celebrity endorsements) and make snap judgments. A trusted politician may declare climate change a hoax. A perfume ad may lure us with images of beautiful or famous people in love.
- **Central route persuasion** offers evidence and arguments that aim to trigger favorable thoughts. It occurs mostly when people are naturally analytical or involved in the issue. Climate scientists marshal evidence of climate warming. An automotive ad may itemize a car's great features. Because it is more thoughtful and less superficial, it is more durable.

Persuaders try to influence our behavior by changing our attitudes. But other factors, including the situation, also influence our behavior. Strong social pressures, for example, can weaken the attitude-behavior connection (Wallace et al., 2005). In roll-call votes, politicians will sometimes vote what their supporters demand, despite privately disagreeing with those demands (Nagourney, 2002). In such cases, external pressure overrides the attitude-behavior link.

Attitudes are especially likely to affect behavior when external influences are minimal, and when the attitude is stable, specific to the behavior, and easily recalled (Glasman & Albarracín, 2006). One experiment used vivid, easily recalled information to persuade people that sustained tanning put them at risk for future skin cancer. One month later, 72 percent of the participants, and only 16 percent of those in a wait-list control group, had lighter skin (McClendon & Prentice-Dunn, 2001). Persuasion changed attitudes, which changed behavior.

Actions Affect Attitudes

Now consider a more surprising principle: Not only will people stand up for what they believe, they also will more strongly believe in what they have stood up for. Many streams of evidence confirm that *attitudes follow behavior* (FIGURE 13.1).

attitude feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events.

peripheral route persuasion occurs when people are influenced by incidental cues, such as a speaker's attractiveness.

central route persuasion occurs when interested people focus on the arguments and respond with favorable thoughts.

▼ FIGURE 13.1

Attitudes follow behavior

Cooperative actions, such as those performed by people on sports teams (including Germany, shown here celebrating their World Cup 2014 victory), feed mutual liking. Such attitudes, in turn, promote positive behavior.

The Foot-in-the-Door Phenomenon How would you react if someone induced you to act against your beliefs? In many cases, people adjust their attitudes. During the Korean war, many U.S. prisoners of war were held in war camps run by Chinese communists. Without using brutality, the captors secured the prisoners' collaboration in various activities. Some merely ran errands or did simple tasks to gain privileges. Others made radio appeals and false confessions. Still others informed on other prisoners and divulged military information. When the war ended, 21 prisoners chose to stay with the communists. More returned home "brainwashed"—convinced that communism was a good thing for Asia.

How did the Chinese captors achieve these amazing results? A key ingredient was their effective use of the **foot-in-the-door phenomenon**: They knew that people who agreed to a small request would find it easier to comply later with a larger one. The Chinese began with harmless requests, such as copying a trivial statement, but gradually escalated their demands (Schein, 1956). The next statement to be copied might list flaws of capitalism. Then, to gain privileges, the prisoners participated in group discussions, wrote self-criticisms, or uttered public confessions. After doing so, they often adjusted their beliefs to be more consistent with their public acts. The point is simple: To get people to agree to something big, start small and build (Cialdini, 1993). A trivial act makes the next act easier. Succumb to a temptation and you will find the next temptation harder to resist.

In dozens of experiments, researchers have coaxed people into acting against their attitudes or violating their moral standards, with the same result: Doing becomes believing. After giving in to a request to harm an innocent victim—by making nasty comments or delivering electric shocks—people begin to disparage their victim. After speaking or writing on behalf of a position they have qualms about, they begin to believe their own words.

Fortunately, the attitudes-follow-behavior principle works with good deeds as well. The foot-in-the-door tactic has helped boost charitable contributions and blood donations, as well as product sales. In one classic experiment, researchers posing as safe-driving volunteers asked Californians to permit the installation of a large, poorly lettered "Drive Carefully" sign in their front yards. Only 17 percent consented. They approached other home owners with a small request first: Would they display a 3-inch-high "Be a Safe Driver" sign? Nearly all readily agreed. When reapproached two weeks later to allow the large, ugly sign in their front yards, 76 percent consented (Freedman

foot-in-the-door phenomenon

the tendency for people who have first agreed to a small request to comply later with a larger request.

"If the King destroys a man, that's proof to the King it must have been a bad man."

Thomas Cromwell, in Robert Bolt's
A Man for All Seasons, 1960

& Fraser, 1966). To secure a big commitment, it often pays to put your foot in the door: Start small and build.

Racial attitudes likewise follow behavior. In the years immediately following the introduction of school desegregation in the United States and the passage of the Civil Rights Act of 1964, White Americans expressed diminishing racial prejudice. And as Americans in different regions came to act more alike—thanks to more uniform national standards against discrimination—they began to think more alike. Experiments confirm the observation: Moral action strengthens moral convictions.

Role Playing Affects Attitudes When you adopt a new **role**—when you become a college student, marry, or begin a new job—you strive to follow the social prescriptions. At first, your behaviors may feel phony, because you are *acting* a role. Soldiers may at first feel they are playing war games. Newlyweds may feel they are “playing house.” Before long, however, what began as playacting in the theater of life becomes *you*. Researchers have confirmed this effect by assessing people’s attitudes before and after they adopt a new role, sometimes in laboratory situations, sometimes in everyday situations, such as before and after taking a job.

Role playing morphed into real life in one famous and controversial study in which male college students volunteered to spend time in a simulated prison. Stanford psychologist Philip Zimbardo (1972) randomly assigned some volunteers to be guards. He gave them uniforms, clubs, and whistles and instructed them to enforce certain rules. Others became prisoners, locked in barren cells and forced to wear humiliating outfits. For a day or two, the volunteers self-consciously “played” their roles. Then the simulation became real—too real. Most guards developed disparaging attitudes, and some devised cruel and degrading routines. One by one, the prisoners broke down, rebelled, or became passively resigned. After only six days, Zimbardo called off the study.

Critics question the reliability of Zimbardo’s results (Griggs, 2014). But this much seems true: Role playing can train torturers (Staub, 1989). In the early 1970s, the Greek military government eased men into their roles. First, a trainee stood guard outside an interrogation cell. After this “foot in the door” step, he stood guard inside. Only then was he ready to become actively involved in the questioning and torture. What we do, we gradually become. In one study of German males, military training toughened their personalities, leaving them less agreeable even five years later after leaving the military (Jackson et al., 2012). And it’s true of us all: Every time we act like the people around us we slightly change ourselves to be more like them, and less like who we used to be.

Yet people differ. In Zimbardo’s Stanford Prison simulation and in other atrocity-producing situations, some people have succumbed to the situation and others have

“Fake it until you make it.”

The power of the situation In his 1972 Stanford Prison simulation, Philip Zimbardo created a toxic situation (left). Those assigned to the guard role soon degraded the prisoners. In real life in 2004, some U.S. military guards tormented Iraqi prisoners at the U.S.-run Abu Ghraib prison (right). To Zimbardo (2004, 2007), it was a bad barrel rather than a few bad apples that led to the Abu Ghraib atrocities: “When ordinary people are put in a novel, evil place, such as most prisons, Situations Win, People Lose.”

AP Photo

not (Carnahan & McFarland, 2007; Haslam & Reicher, 2007, 2012; Mastroianni & Reed, 2006; Zimbardo, 2007). Person and situation interact. Much as water dissolves salt but not sand, so rotten situations turn some people into bad apples while others resist (Johnson, 2007).

Cognitive Dissonance: Relief From Tension So far, we have seen that actions can affect attitudes, sometimes turning prisoners into collaborators, doubters into believers, and compliant guards into abusers. But why? One explanation is that when we become aware that our attitudes and actions don't coincide, we experience tension, or *cognitive dissonance*. Indeed, the brain regions that become active when people experience cognitive conflict and negative arousal also become active when people experience cognitive dissonance (Kitayama et al., 2013). To relieve this tension, according to Leon Festinger's (1957) **cognitive dissonance theory**, we often bring our attitudes into line with our actions.

Dozens of experiments have explored this cognitive dissonance phenomenon. Many have made people feel responsible for behavior that clashed with their attitudes and had foreseeable consequences. In one of these experiments, you might agree for a measly \$2 to help a researcher by writing an essay that supports something you don't believe in (perhaps a tuition increase). Feeling responsible for the statements (which are inconsistent with your attitudes), you would probably feel dissonance, especially if you thought an administrator would be reading your essay. To reduce the uncomfortable tension you might start believing your phony words. At such times, it's as if we rationalize, "If I chose to do it (or say it), I must believe in it." The less coerced and more responsible we feel for a troubling act, the more dissonance we feel. The more dissonance we feel, the more motivated we are to find consistency, such as changing our attitudes to help justify the act.

The attitudes-follow-behavior principle has a heartening implication: We cannot directly control all our feelings, but we can influence them by altering our behavior. If we are down in the dumps, we can do as cognitive-behavioral therapists advise and talk in more positive, self-accepting ways with fewer self-put-downs. If we are unloving, we can become more loving by behaving as if we were so—by doing thoughtful things, expressing affection, giving affirmation. That helps explain why teens' doing volunteer work promotes a compassionate identity. "Assume a virtue, if you have it not," says Hamlet to his mother. "For use can almost change the stamp of nature." Pretense can become reality. Conduct sculpts character. What we do we become.

The point to remember: Cruel acts shape the self. But so do acts of good will. Act as though you like someone, and you soon may. Changing our behavior can change how we think about others and how we feel about ourselves.

role a set of expectations (norms) about a social position, defining how those in the position ought to behave.

cognitive dissonance theory the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes.

 **LaunchPad** To check your understanding of cognitive dissonance, visit LaunchPad's **Concept Practice: Cognitive Dissonance**.

"Sit all day in a moping posture, sigh, and reply to everything with a dismal voice, and your melancholy lingers. . . . If we wish to conquer undesirable emotional tendencies in ourselves, we must . . . go through the outward movements of those contrary dispositions which we prefer to cultivate."

William James, *Principles of Psychology*, 1890

RETRIEVAL PRACTICE

- Driving to school one snowy day, Marco narrowly misses a car that slides through a red light. "Slow down! What a terrible driver," he thinks to himself. Moments later, Marco himself slips through an intersection and yelps, "Wow! These roads are awful. The city plows need to get out here." What social psychology principle has Marco just demonstrated? Explain.
ANSWER: By attributing the other person's behavior to the person ("he's a terrible driver") and his own situation ("these roads are awful"), Marco has exhibited the *fundamental attribution error*.
- How do our attitudes and our actions affect each other?
ANSWER: Our attitudes often influence our actions as we behave in ways consistent with our beliefs. However, our attitudes also follow our actions; we come to believe in what we have done.
- When people act in a way that is not in keeping with their attitudes, and then change their attitudes to match those actions, _____ theory attempts to explain why.
ANSWER: cognitive dissonance

Social Influence

“Have you ever noticed how one example—good or bad—can prompt others to follow? How one illegally parked car can give permission for others to do likewise? How one racial joke can fuel another?”

Marian Wright Edelman,
The Measure of Our Success, 1992

Social psychology's great lesson is the enormous power of social influence. This influence can be seen in our conformity, our obedience to authority, and our group behavior. Suicides, bomb threats, airplane hijackings, and UFO sightings all have a curious tendency to come in clusters. On campus, jeans are the dress code; on New York's Wall Street or London's Bond Street, dress suits are the norm. When we know how to act, how to groom, how to talk, life functions smoothly. Armed with social influence principles, advertisers, fundraisers, and campaign workers aim to sway our decisions to buy, to donate, to vote. Isolated with others who share their grievances, dissenters may gradually become rebels, and rebels may become terrorists. Let's examine the pull of these social strings. How strong are they? How do they operate? When do we break them?

Conformity: Complying With Social Pressures

13-3 What is automatic mimicry, and how do conformity experiments reveal the power of social influence?

Automatic Mimicry

Fish swim in schools. Birds fly in flocks. And humans, too, tend to go with their group, to think what it thinks and do what it does. Behavior is contagious. Chimpanzees are more likely to yawn after observing another chimpanzee yawn (Anderson et al., 2004). Ditto for humans. If one of us yawns, laughs, coughs, stares at the sky, or checks a cell phone, others in our group will often do the same. Yawn mimicry can also occur across species: Dogs more often yawn after observing their owners' yawn (Silva et al., 2012). Even just reading about yawning increases people's yawning (Provine, 2012), as perhaps you have noticed?

“Look, I have my misgivings, too, but what choice do we have except stay the course?”

Like the chameleon lizards that take on the color of their surroundings, we humans take on the emotional tones of those around us. Just hearing someone reading a neutral text in either a happy- or sad-sounding voice creates “mood contagion” in listeners (Neumann & Strack, 2000). We are natural mimics, unconsciously imitating others’ expressions, postures, and voice tones.

Tanya Chartrand and John Bargh captured this mimicry, which they call the *chameleon effect* (Chartrand & Bargh, 1999). They had students work in a room alongside another person, who was actually a confederate working for the experimenters. Sometimes the confederates rubbed their own face. Sometimes they shook their foot. Sure enough, the students tended to rub their face when with the face-rubbing person and shake their foot when with the foot-shaking person. Other studies have found people synchronizing their grammar to match material they are reading or people they are hearing (Ireland & Pennebaker, 2010).

We should not be surprised, then, that intricate studies show that obesity, sleep loss, drug use, loneliness, and happiness spread through social networks (Christakis & Fowler, 2009). We and our friends form a social system. On websites, positive ratings generate more positive ratings—a phenomenon called “positive herding” (Muchnik et al., 2013). In a massive experiment on the 2010 U.S. congressional election day, Facebook showed 61 million people a message that encouraged their voting, with a link to a local voting place and a clickable “I voted” button. Those who also received these messages with pictures of Facebook friends who had already voted became slightly more likely to vote—enough so to have generated an estimated 282,000 additional voters (FIGURE 13.2).

Automatic mimicry helps us to *empathize*—to feel what others are feeling. This helps explain why we feel happier around happy people than around depressed people. It also helps explain why studies of groups of British workers have revealed *mood linkage*, or the sharing of moods (Totterdell et al., 1998). Empathic people yawn more after seeing others yawn (Morrison, 2007). And empathic mimicking fosters fondness (van Baaren et al., 2003, 2004). Perhaps you’ve noticed that when someone nods their head as you do and echoes your words, you feel a certain rapport and liking?

Suggestibility and mimicry sometimes lead to tragedy. In the eight days following the 1999 shooting rampage at Colorado’s Columbine High School, every U.S. state except Vermont experienced threats of copycat violence. Pennsylvania alone recorded 60 such threats (Cooper, 1999). Sociologist David Phillips and his colleagues (1985, 1989) found that suicides, too, sometimes increase following a highly publicized suicide. In the wake of screen idol Marilyn Monroe’s suicide on August 5, 1962, for example, the number of suicides in the United States exceeded the usual August count by 200.

Conforming to nonconformity Are these students asserting their individuality or identifying themselves with others of the same microculture?

“When I see synchrony and mimicry—whether it concerns yawning, laughing, dancing, or aping—I see social connection and bonding.”

Primatologist Frans de Waal
“The Empathy Instinct,” 2009

▼ **FIGURE 13.2**
Social networking influence On the 2010 U.S. congressional election day, Facebook gave people an *informational message* that encouraged voting. The message had measurably more influence when supplemented with a *social message* that showed friends who had voted (Bond et al., 2012).

NON SEQUITUR

by WILEY

conformity adjusting our behavior or thinking to coincide with a group standard.

normative social influence influence resulting from a person's desire to gain approval or avoid disapproval.

informational social influence influence resulting from one's willingness to accept others' opinions about reality.

What causes behavior clusters? Do people act similarly because of their influence on one another? Or because they are simultaneously exposed to the same events and conditions? Seeking answers to such questions, social psychologists have conducted experiments on group pressure and conformity.

Conformity and Social Norms

Suggestibility and mimicry are subtle types of **conformity**—adjusting our behavior or thinking toward some group standard. To study conformity, Solomon Asch (1955) devised a simple test. Imagine yourself as a participant in what you believe is a study of visual perception. You arrive in time to take a seat at a table with five other people. The experimenter asks the group to state, one by one, which of three comparison lines is identical to a standard line. You see clearly that the answer is Line 2, and you await your turn to say so. Your boredom begins to show when the next set of lines proves equally easy.

Now comes the third trial, and the correct answer seems just as clear-cut (**FIGURE 13.3**). But the first person gives what strikes you as a wrong answer: “Line 3.” When the second person and then the third and fourth give the same wrong answer, you sit up straight and squint. When the fifth person agrees with the first four, you feel your heart begin to pound. The experimenter then looks to you for your answer. Torn between the unanimity voiced by the five others and the evidence of your own eyes, you feel tense and suddenly unsure. You hesitate before answering, wondering whether you should suffer the discomfort of being the oddball. What answer do you give?

In Asch's experiments, college students, answering questions alone, erred less than 1 percent of the time. But what about when several others—“confederates” working for the experimenter—answered incorrectly? Although most people told the truth even when others did not, Asch was disturbed by his result: More than one-third of the time, these “intelligent and well-meaning” college students were “willing to call white black” by going along with the group.

▼ FIGURE 13.3

Asch's conformity experiments

Which of the three comparison lines is equal to the standard line? What do you suppose most people would say after hearing five others say, “Line 3”? In this photo from one of Asch's experiments, the student in the center shows the severe discomfort that comes from disagreeing with the responses of other group members (in this case, accomplices of the experimenter).

William Vandivert/Scientific American

Later investigations have not always found as much conformity as Asch found, but they have revealed that we are more likely to conform when we

- are made to feel incompetent or insecure.
- are in a group with at least three people.
- are in a group in which everyone else agrees. (If just one other person disagrees, the odds of our disagreeing greatly increase.)
- admire the group's status and attractiveness.
- have not made a prior commitment to any response.
- know that others in the group will observe our behavior.
- are from a culture that strongly encourages respect for social standards.

Why do we so often think what others think and do what they do? Why, in college residence halls, do students' attitudes become more similar to those living near them (Cullum & Harton, 2007)? Why, when asked controversial questions, are students' answers more diverse when using anonymous electronic clickers than when raising hands (Stowell et al., 2010)? Why do we clap when others clap, eat as others eat, believe what others believe, say what others say, even see what others see?

Frequently, we conform to avoid rejection or to gain social approval. In such cases, we are responding to **normative social influence**. We are sensitive to *social norms*—understood rules for accepted and expected behavior—because the price we pay for being different can be severe. We need to belong.

At other times, we conform because we want to be accurate. Groups provide information, and only an uncommonly stubborn person will never listen to others. “Those who never retract their opinions love themselves more than they love truth,” observed Joseph Joubert, an eighteenth-century French essayist. When we accept others' opinions about reality, we are responding to **informational social influence**. As Rebecca Denton demonstrated in 2004, sometimes it pays to assume others are right and to follow their lead. Denton set a record for the farthest distance driven on the wrong side of a British divided highway—30 miles, with only one minor sideswipe, before the motorway ran out and police were able to puncture her tires. Denton, who was intoxicated, later explained that she thought the hundreds of other drivers coming at her were all on the wrong side of the road (Woolcock, 2004).

Is conformity good or bad? The answer depends partly on our culturally influenced values. Western Europeans and people in most English-speaking countries tend to prize individualism. People in many Asian, African, and Latin American countries place a higher value on honoring group standards. In social influence experiments across 17 countries, conformity rates have been lower in individualist cultures (Bond & Smith, 1996). American university students, for example, tend to see themselves, in domains ranging from consumer purchases to political views, as less conforming than others (Pronin et al., 2007). We are, in our own eyes, individuals amid a crowd of sheep.

RETRIEVAL PRACTICE

- Which of the following strengthens conformity to a group?
 - a. Finding the group attractive
 - b. Feeling secure
 - c. Coming from an individualist culture
 - d. Having made a prior commitment

ANSWER: a

“I love the little ways you're identical to everyone else.”

Like humans, migrating and herding animals conform for both informational and normative reasons (Claidière & Whiten, 2012). Following others is informative; compared with solo geese, a flock of geese migrate more accurately. (There is wisdom in the crowd.) But staying with the herd also sustains group membership.

Obedience: Following Orders

13-4 What did Milgram's obedience experiments teach us about the power of social influence?

Social psychologist Stanley Milgram (1963, 1974), a high school classmate of Philip Zimbardo and then a student of Solomon Asch, knew that people often give in to social pressures. But how would they respond to outright commands? To find out, he undertook what became social psychology's most famous and controversial experiments (Benjamin & Simpson, 2009).

Imagine yourself as one of the nearly 1000 people who took part in Milgram's 20 experiments. You respond to an advertisement for participants in a Yale University psychology study of the effect of punishment on learning. Professor Milgram's assistant asks you and another person to draw slips from a hat to see who will be the "teacher" and who will be the "learner." Because (unknown to you) both slips say "teacher," you draw a "teacher" slip and are asked to sit down in front of a machine, which has a series of labeled switches. The supposed learner, a mild and submissive-seeming man, is led to an adjoining room and strapped into a chair. From the chair, wires run through the wall to "your" machine. You are given your task: Teach and then test the learner on a list of word pairs. If the learner gives a wrong answer, you are to flip a switch to deliver a brief electric shock. For the first wrong answer, you will flip the switch labeled "15 Volts—Slight Shock." With each succeeding error, you will move to the next higher voltage. With each flip of a switch, lights flash and electronic switches buzz.

The experiment begins, and you deliver the shocks after the first and second wrong answers. If you continue, you hear the learner grunt when you flick the third, fourth, and fifth switches. After you activate the eighth switch ("120 Volts—Moderate Shock"), the learner cries out that the shocks are painful. After the tenth switch ("150 Volts—Strong Shock"), he begins shouting. "Get me out of here! I won't be in the experiment anymore! I refuse to go on!" You draw back, but the stern experimenter prods you: "Please continue—the experiment requires that you continue." You resist, but the experimenter insists, "It is absolutely essential that you continue," or "You have no other choice, you *must* go on."

If you obey, you hear the learner shriek in apparent agony as you continue to raise the shock level after each new error. After the 330-volt level, the learner refuses to answer and falls silent. Still, the experimenter pushes you toward the final, 450-volt switch. Ask the question, he says, and if no correct answer is given, administer the next shock level.

Would you follow the experimenter's commands to shock someone? At what level would you refuse to obey? Before undertaking the experiments, Milgram asked people what they would do. Most people were sure they would stop soon after the learner first indicated pain, certainly before he shrieked in agony. Forty psychiatrists agreed with that prediction when Milgram asked them. Were the predictions accurate? Not even close. When Milgram conducted the experiment with other men aged 20 to 50, he was astonished. More than 60 percent complied fully—right up to the last switch. When he ran a new study, with 40 new "teachers" and a learner who complained of a "slight heart condition," the results were similar. A full 65 percent of the new teachers obeyed the experimenter right up to 450 volts (**FIGURE 13.4**). In 10 later studies, women obeyed at rates similar to men's (Blass, 1999).

Cultures change over time. Researchers wondered if Milgram's results could be explained by the 1960s American mind-set. To find out, Jerry Burger (2009) replicated Milgram's basic experiment. Seventy percent of the participants obeyed up to the 150-volt point, only a slight reduction from Milgram's result. And in a recent French reality TV show replication, 81 percent of people, egged on by a cheering audience, obeyed and tortured a screaming victim (Beauvois et al., 2012).

Stanley Milgram (1933–1984)

This social psychologist's obedience experiments "belong to the self-understanding of literate people in our age" (Sabini, 1986).

▼ FIGURE 13.4

Milgram's follow-up obedience experiment

In a repeat of the earlier experiment, 65 percent of the adult male "teachers" fully obeyed the experimenter's commands to continue. They did so despite the "learner's" earlier mention of a heart condition and despite hearing cries of protest after they administered what they thought were 150 volts and agonized protests after 330 volts. (Data from Milgram, 1974.)

Did Milgram's teachers figure out the hoax—that no real shock was being delivered and the learner was in fact a confederate who was pretending to feel pain? Did they realize the experiment was really testing their willingness to comply with commands to inflict punishment? No. The teachers typically displayed genuine distress: They perspired, trembled, laughed nervously, and bit their lips.

Milgram's use of deception and stress triggered a debate over his research ethics. In his own defense, Milgram pointed out that, after the participants learned of the deception and actual research purposes, virtually none regretted taking part (though perhaps by then the participants had reduced their cognitive dissonance—the discomfort they felt when their actions conflicted with their attitudes). When 40 of the teachers who had agonized most were later interviewed by a psychiatrist, none appeared to be suffering emotional aftereffects. All in all, said Milgram, the experiments provoked less enduring stress than university students experience when facing and failing big exams (Blass, 1996). Other scholars, however, after delving into Milgram's archives, report that his debriefing was less extensive and his participants' distress greater than what he had suggested (Nicholson, 2011; Perry, 2013).

In later experiments, Milgram discovered some conditions that influence people's behavior. When he varied the situation, the percentage of participants who obeyed fully ranged from 0 to 93 percent. Obedience was highest when

- *the person giving the orders was close at hand and was perceived to be a legitimate authority figure.* Such was the case in 2005 when Temple University's basketball coach sent a 250-pound bench player, Nehemiah Ingram, into a game with instructions to commit "hard fouls." Following orders, Ingram fouled out in four minutes after breaking an opposing player's right arm.
- *the authority figure was supported by a prestigious institution.* Compliance was somewhat lower when Milgram dissociated his experiments from Yale University. People have wondered: Why, during the 1994 Rwandan genocide, did so many Hutu citizens slaughter their Tutsi neighbors? It was partly because they were part of "a culture in which orders from above, even if evil," were understood as having the force of law (Kamatali, 2014).
- *the victim was depersonalized or at a distance, even in another room.* Similarly, many soldiers in combat either have not fired their rifles at an enemy they can see, or

Standing up for democracy

Some individuals—roughly one in three in Milgram’s experiments—resist social coercion, as did this unarmed man in Beijing, by single-handedly challenging an advancing line of tanks the day after the 1989 Tiananmen Square student uprising was suppressed.

have not aimed them properly. Such refusals to kill have been rare among soldiers who were operating long-distance artillery or aircraft weapons (Padgett, 1989). Those who killed from a distance—by operating remotely piloted drones—also have suffered much less posttraumatic stress than have on-the-ground Afghanistan and Iraq War veterans (Miller, 2012).

- *there were no role models for defiance.* “Teachers” did not see any other participant disobey the experimenter.

The power of legitimate, close-at-hand authorities was apparent among those who followed orders to carry out Holocaust atrocities. While obedience alone does not explain the Holocaust, in which anti-Semitic ideology also played a role, it was a significant factor.

In the summer of 1942, nearly 500 middle-aged German reserve police officers were dispatched to German-occupied Jozefow, Poland. On July 13, the group’s visibly upset commander informed his recruits, mostly family men, of their orders. They were to round up the village’s Jews, who were said to be aiding the enemy. Able-bodied men would be sent to work camps, and the rest would be shot on the spot.

The commander gave the recruits a chance to refuse to participate in the executions. Only about a dozen immediately refused. Within 17 hours, the remaining 485 officers killed 1500 helpless women, children, and elderly, shooting them in the back of the head as they lay face down. Hearing the victims’ pleas, and seeing the gruesome results, some 20 percent of the officers did eventually dissent, managing either to miss their victims or to wander away and hide until the slaughter was over (Browning, 1992). In real life, as in Milgram’s experiments, those who resisted did so early, and they were the minority.

A different story played out in the French village of Le Chambon. There, villagers openly defied orders to cooperate with the “New Order” by sheltering French Jews, who were destined for deportation to Germany. The villagers’ Protestant ancestors had themselves been persecuted, and their pastors taught them to “resist whenever our adversaries will demand of us obedience contrary to the orders of the Gospel” (Rochat, 1993). Ordered by police to give a list of sheltered Jews, the head pastor modeled defiance: “I don’t know of Jews, I only know of human beings.” Without realizing how long and terrible the war would be, or how much punishment and poverty they would suffer, the resisters made an initial commitment to resist. Supported by their beliefs, their role models, their interactions with one another, and their own initial acts, they remained defiant to the war’s end.

Lest we presume that obedience is always evil and resistance is always good, consider the obedience of British soldiers who, in 1852, were traveling with civilians aboard the steamship *Birkenhead*. As they neared their South African port, the *Birkenhead* became impaled on a rock. To calm the passengers and permit an orderly exit of civilians on the three available lifeboats, soldiers who were not assisting the passengers or working the pumps lined up at parade rest. “Steady, men!” said their officer as the lifeboats pulled away. Heroically, no one frantically rushed to claim a lifeboat seat. As the boat sank, all were plunged into the sea, most to be drowned or devoured by sharks. For almost a century, noted James Michener (1978), “the Birkenhead drill remained the measure by which heroic behavior at sea was measured.”

The Wreck of HMS Birkenhead off the Cape of Good Hope on 26 Feb. 1852, 1892 (litho) (later colouration). Henry, Thomas Marie Madawaska (1852–1937)/The Argory, County Armagh, Northern Ireland/Bridgeman

The “Birkenhead drill” To calm and give priority to passengers, soldiers obeyed orders to line up on deck as their ship sank.

Lessons From the Obedience Studies

What do the Milgram experiments teach us about ourselves? How does flicking a shock switch relate to everyday social behavior? Psychological experiments aim not to re-create the literal behaviors of everyday life but to capture and explore the underlying processes that shape those behaviors. Participants in Milgram's experiments confronted a dilemma we all face frequently: Do I adhere to my own standards, or do I respond to others?

In Milgram's experiments and their modern replications, participants were torn. Should they respond to the pleas of the victim or the orders of the experimenter? Their moral sense warned them not to harm another, yet it also prompted them to obey the experimenter and to be a good research participant. With kindness and obedience on a collision course, obedience usually won.

These experiments demonstrated that strong social influences can make people conform to falsehoods or capitulate to cruelty. Milgram saw this as the fundamental lesson of this work: "Ordinary people, simply doing their jobs, and without any particular hostility on their part, can become agents in a terrible destructive process" (1974, p. 6).

Focusing on the end point—450 volts, or someone's real-life violence—we can hardly comprehend the inhumanity. But we ignore how they get there, in tiny increments. Milgram did not entrap his teachers by asking them first to zap learners with enough electricity to make their hair stand on end. Rather, he exploited the foot-in-the-door effect, beginning with a little tickle of electricity and escalating step by step. In the minds of those throwing the switches, the small action became justified, making the next act tolerable. In Jozefow and Le Chambon, as in Milgram's experiments, those who resisted usually did so early. After the first acts of compliance or resistance, attitudes began to follow and justify behavior.

So it happens when people succumb, gradually, to evil. In any society, great evils often grow out of people's compliance with lesser evils. The Nazi leaders suspected that most German civil servants would resist shooting or gassing Jews directly, but they found them surprisingly willing to handle the paperwork of the Holocaust (Silver & Geller, 1978). Milgram found a similar reaction in his experiments. When he asked 40 men to administer the learning test while someone else did the shocking, 93 percent complied. Cruelty does not require devilish villains. All it takes is ordinary people corrupted by an evil situation. Ordinary students may follow orders to haze initiates into their group. Ordinary employees may follow orders to produce and market harmful products. Ordinary soldiers may follow orders to punish and then torture prisoners (Lankford, 2009).

"I was only following orders."

RETRIEVAL PRACTICE

- Psychology's most famous obedience experiments, in which most participants obeyed an authority figure's demands to inflict presumed painful, dangerous shocks on an innocent participant, were conducted by social psychologist _____.

ANSWER: Stanley Milgram

- What situations have researchers found to be most likely to encourage obedience in participants?

ANSWER: The Milgram studies showed that people were most likely to follow orders when the experimenter was nearby and was a legitimate authority figure, the victim was not nearby, and there were no models for defiance.

Group Behavior

13-5 How is our behavior affected by the presence of others?

Imagine standing in a room, holding a fishing pole. Your task is to wind the reel as fast as you can. On some occasions you wind in the presence of another participant, who is also winding as fast as possible. Will the other's presence affect your own performance?

Social facilitation Skilled athletes often find they are “on” before an audience. What they do well, they do even better when people are watching.

In one of social psychology’s first experiments, Norman Triplett (1898) reported that adolescents would wind a fishing reel faster in the presence of someone doing the same thing. Although a modern reanalysis revealed that the difference was modest (Stroebe, 2012), Triplett inspired later social psychologists to study how others’ presence affects our behavior. Group influences operate both in simple groups—one person in the presence of another—and in more complex groups.

Social Facilitation

Triplett’s claim—of strengthened performance in others’ presence—is called **social facilitation**. But on tougher tasks (learning nonsense syllables or solving complex multiplication problems), people perform worse when observers or others working on the same task are present. Further studies revealed that the presence of others sometimes helps and sometimes hinders performance (Guerin, 1986; Zajonc, 1965). Why? Because when others observe us, we become aroused, and this arousal amplifies our other reactions. It strengthens our most *likely* response—the correct one on an easy task, an incorrect one on a difficult task. Thus, expert pool players who made 71 percent of their shots when alone made 80 percent when four people came to watch them (Michaels et al., 1982). Poor shooters, who made 36 percent of their shots when alone, made only 25 percent when watched.

The energizing effect of an enthusiastic audience probably contributes to the home advantage that has shown up in studies of more than a quarter-million college and professional athletic events in various countries (Allen & Jones, 2014; Jamieson, 2010). Home teams win about 6 in 10 games (somewhat fewer for baseball, cricket, and American football, somewhat more for basketball, rugby, and soccer—see **TABLE 13.1**). For most sports, home cooking is best.

Social facilitation also helps explain a funny effect of crowding. Comedians and actors know that a “good house” is a full one. Crowding triggers arousal. Comedy routines that are mildly amusing in an uncrowded room seem funnier in a densely packed room (Aiello et al., 1983; Freedman & Perlick, 1979). In experiments, when seated close to one another, participants like a friendly person even more and an unfriendly person even less (Schiffenbauer & Schiavo, 1976; Storms & Thomas, 1977). So, to ensure an energetic class or event, choose a room or set up seating that will just barely accommodate everyone.

▼ **TABLE 13.1**
Home Advantage in Team Sports

Sport	Years	Home games won
Nippon League Baseball	1998–2009	53.6%
Major League Baseball	1903–2009	53.9%

English Premier League Soccer	1993–2009	63.0%
NCAA Men’s Basketball	1947–2009	68.8%
Major League Soccer	2002–2009	69.1%

Source: Data from Moskowitz & Wertheim, 2011.

social facilitation improved performance on simple or well-learned tasks in the presence of others.

social loafing the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable.

deindividuation the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity.

The point to remember: What you do well, you are likely to do even better in front of an audience, especially a friendly audience. What you normally find difficult may seem all but impossible when you are being watched.

Social Loafing

Social facilitation experiments test the effect of others' presence on performance of an individual task, such as shooting pool. But what happens when people perform as a group? In a team tug-of-war, would your effort be more than, less than, or the same as the effort you would exert in a one-on-one tug-of-war?

To find out, a University of Massachusetts research team asked blindfolded students "to pull as hard as you can" on a rope. When they fooled the students into believing three others were also pulling behind them, students exerted only 82 percent as much effort as when they knew they were pulling alone (Ingham et al., 1974). And consider what happened when blindfolded people seated in a group clapped or shouted as loudly as they could while hearing (through headphones) other people clapping or shouting loudly (Latané, 1981). When they thought they were part of a group effort, the participants produced about one-third less noise than when clapping or shouting "alone."

Bibb Latané and his colleagues (1981; Jackson & Williams, 1988) described this diminished effort as **social loafing**. Experiments in the United States, India, Thailand, Japan, China, and Taiwan have found social loafing on various tasks, though it was especially common among men in individualist cultures (Karau & Williams, 1993). What causes social loafing? Three things:

- People acting as part of a group feel *less accountable*, and therefore worry less about what others think.
- Group members may view their individual contributions as *dispensable* (Harkins & Szymanski, 1989; Kerr & Bruun, 1983).
- When group members share equally in the benefits, regardless of how much they contribute, some may slack off (as you perhaps have observed on group assignments). Unless highly motivated and strongly identified with the group, people may *free ride* on others' efforts.

Deindividuation

We've seen that the presence of others can arouse people (social facilitation), or it can diminish their feelings of responsibility (social loafing). But sometimes the presence of others does both. The uninhibited behavior that results can range from a food fight to vandalism or rioting. This process of losing self-awareness and self-restraint, called **deindividuation**, often occurs when group participation makes people both *aroused* and *anonymous*. In one experiment, New York University women dressed in depersonalizing Ku Klux Klan-style hoods. Compared with identifiable women in a control group, the hooded women delivered twice as much electric shock to a victim (Zimbardo, 1970). (As in all such experiments, the "victim" did not actually receive the shocks.)

Deindividuation thrives, for better or for worse, in many settings. Tribal warriors who depersonalize themselves with face paints or masks are more likely than those with exposed faces to kill, torture, or mutilate captured enemies (Watson, 1973). On discussion boards, Internet bullies, who would never say "You're so fake" to someone's face, may hide behind anonymity. When we shed self-awareness and self-restraint—whether in a mob, at a rock concert, at a ballgame, or at worship—we become more responsive to the group experience, whether bad or good. For a comparison of social facilitation, social loafing, and deindividuation, see TABLE 13.2 on the next page.

Lawrence Migdale/Photo Researchers, Inc.

Working hard, or hardly working?

In group projects, such as this Earth Day beach cleanup, social loafing often occurs, as individuals free ride on the efforts of others.

Deindividuation During England's 2011 riots and looting, rioters were disinhibited by social arousal and by the anonymity provided by darkness and their hoods and masks. Later, some of those arrested expressed bewilderment over their own behavior.

Lewis Whyld/PA Wire/Press Association/AP Images

▼ TABLE 13.2
Behavior in the Presence of Others: Three Phenomena

Phenomenon	Social context	Psychological effect of others' presence	Behavioral effect
<i>Social facilitation</i>	Individual being observed	Increased arousal	Amplified dominant behavior, such as doing better what one does well (or doing worse what is difficult)
<i>Social loafing</i>	Group projects	Diminished feelings of responsibility when not individually accountable	Decreased effort
<i>Deindividuation</i>	Group setting that fosters arousal and anonymity	Reduced self-awareness	Lowered self-restraint

▼ FIGURE 13.5
Group polarization If a group is like-minded, discussion strengthens its prevailing opinions. Talking over racial issues increased prejudice in a high-prejudice group of high school students and decreased it in a low-prejudice group. (Data from Myers & Bishop, 1970.)

“What explains the rise of fascism in the 1930s? The emergence of student radicalism in the 1960s? The growth of Islamic terrorism in the 1990s? . . . The unifying theme is simple: *When people find themselves in groups of like-minded types, they are especially likely to move to extremes.* [This] is the phenomenon of *group polarization*.”

Cass Sunstein, *Going to Extremes*, 2009

We have examined the conditions under which the *presence* of others can motivate people to exert themselves or tempt them to free ride on the efforts of others, make easy tasks easier and difficult tasks harder, and enhance humor or fuel mob violence. Research also shows that *interacting* with others can similarly have both bad and good effects.

Group Polarization

13-6 What are *group polarization* and *groupthink*, and how much power do we have as individuals?

Over time, initial differences between groups of college students tend to grow. If the first-year students at College X tend to be artistic, and those at College Y tend to be business-savvy, those differences will probably be even greater by the time they graduate. Similarly, gender differences tend to widen over time, as Eleanor Maccoby (2002) noted from her decades of observing gender development. Girls talk more intimately than boys do and play and fantasize less aggressively; these differences will be amplified as boys and girls interact mostly with their own gender.

In each case, the beliefs and attitudes we bring to a group grow stronger as we discuss them with like-minded others. This process, called **group polarization**, can have beneficial results, as when it amplifies a sought-after spiritual awareness or reinforces the resolve of those in a self-help group. But it can also have dire consequences. George Bishop and I [DM] discovered that when high-prejudice students discussed racial issues, they became *more* prejudiced (FIGURE 13.5). Low-prejudice students, alternatively, became even more accepting.

Group polarization can feed extremism and even suicide terrorism. Analyses of terrorist organizations around the world reveal that the terrorist mentality does not erupt suddenly, on a whim (McCauley, 2002; McCauley & Segal, 1987; Merari, 2002). It usually begins slowly, among people who share a grievance. As they interact in isolation (sometimes with other “brothers” and “sisters” in camps) their views grow more and more extreme. Increasingly, they categorize the world as “us” against “them” (Moghaddam, 2005; Qirko, 2004). Given that the self-segregation of the like-minded polarizes people, speculated a 2006 U.S. National Intelligence estimate: “We assess that the operational threat from self-radicalized cells will grow.”

When I got my start in social psychology with experiments on group polarization, I never imagined the potential dangers, or the creative possibilities, of polarization in *virtual* groups. Electronic communication and social networking have created virtual town halls where people can isolate themselves from those with different perspectives. By attuning our bookmarks and social media feeds to sites that trash the views

we despise, we can retreat into partisan tribes and revel in foregone conclusions. People read blogs that reinforce their views, and those blogs link to kindred blogs (FIGURE 13.6). Over time, the resulting political polarization—“loathing across party lines,” say some political scientists (Iyengar & Westwood, 2014)—has become much more intense than racial polarization.

As the Internet connects the like-minded and pools their ideas, climate-change skeptics, UFO abductees, and conspiracy theorists find support for their shared ideas and suspicions. White supremacists may become more racist. And militia members may become more terror prone. The longer participants spend in closed “Dark Web” forums, the more violent their messages become (Chen, 2012). Boston Marathon bombers Dzhokhar and Tamerlan Tsarnaev reportedly were “self-radicalized” through their Internet participation (Wilson et al., 2013). In the echo chambers of virtual worlds, as in the real world, separation + conversation = polarization.

But the Internet-as-social-amplifier can also work for good. Social networking sites connect friends and family members sharing common interests or coping with similar challenges. Peacemakers, cancer survivors, and bereaved parents can find strength and solace from kindred spirits. By amplifying shared concerns and ideas, Internet-enhanced communication can also foster social ventures. (I [DM] know this personally from social networking with others with hearing loss in an effort to transform American listening technology.)

The point to remember: By connecting and magnifying the inclinations of like-minded people, the Internet can be very, very bad, but also very, very good.

Groupthink

So, group interaction can influence our personal decisions. Does it ever distort important national decisions? Consider the “Bay of Pigs fiasco.” In 1961, President John F. Kennedy and his advisers decided to invade Cuba with 1400 CIA-trained Cuban exiles. When the invaders were easily captured and soon linked to the U.S. government, Kennedy wondered in hindsight, “How could we have been so stupid?”

Social psychologist Irving Janis (1982) studied the decision-making procedures leading to the ill-fated invasion. He discovered that the soaring morale of the recently elected president and his advisers fostered undue confidence. To preserve the good feeling, group members suppressed or self-censored their dissenting views, especially after President Kennedy voiced his enthusiasm for the scheme. Since no one spoke strongly against the idea, everyone assumed the support was unanimous. To describe this harmonious but unrealistic group thinking, Janis coined the term **groupthink**.

Later studies showed that groupthink—fed by overconfidence, conformity, self-justification, and group polarization—contributed to other fiascos as well. Among them were the failure to anticipate the 1941 Japanese attack on Pearl Harbor; the escalation of the Vietnam war; the U.S. Watergate cover-up; the Chernobyl nuclear reactor accident (Reason, 1987); the U.S. space shuttle *Challenger* explosion (Esser & Lindoerfer, 1989); and the Iraq war, launched on the false idea that Iraq had weapons of mass destruction (U.S. Senate Intelligence Committee, 2004).

▼ **FIGURE 13.6**
Like minds network in the blogosphere Blue liberal blogs link mostly to one another, as do red conservative blogs. (The intervening colors display links across the liberal-conservative boundary.) Each dot represents a blog, and each dot's size reflects the number of other blogs linking to that blog. (From Lazer et al., 2009.)

Frank Cothran/The New Yorker Collection/Condé Nast

“I wonder if we might benefit from socializing more with those who don’t harbor anti-government views.”

“One of the dangers in the White House, based on my reading of history, is that you get wrapped up in groupthink and everybody agrees with everything, and there’s no discussion and there are no dissenting views.”

Barack Obama, December 1, 2008, press conference

group polarization the enhancement of a group’s prevailing inclinations through discussion within the group.

groupthink the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives.

“Truth springs from argument among friends.”

Philosopher David Hume, 1711–1776

“If you have an apple and I have an apple and we exchange apples then you and I will still each have one apple. But if you have an idea and I have an idea and we exchange these ideas, then each of us will have two ideas.”

Attributed to dramatist
George Bernard Shaw, 1856–1950

Despite the dangers of groupthink, two heads are often better than one. Knowing this, Janis also studied instances in which U.S. presidents and their advisers collectively made good decisions, such as when the Truman administration formulated the Marshall Plan, which offered assistance to Europe after World War II, and when the Kennedy administration successfully prevented the Soviets from installing missiles in Cuba. In such instances—and in the business world, too, Janis believed—groupthink is prevented when a leader welcomes various opinions, invites experts’ critiques of developing plans, and assigns people to identify possible problems. Just as the suppression of dissent bends a group toward bad decisions, open debate often shapes good ones. This is especially the case with diverse groups, whose varied perspectives often enable creative or superior outcomes (Nemeth & Ormiston, 2007; Page, 2007). None of us is as smart as all of us.

The Power of Individuals

In affirming the power of social influence, we must not overlook the power of individuals. *Social control* (the power of the situation) and *personal control* (the power of the individual) interact. People aren’t billiard balls. When feeling coerced, we may react by doing the opposite of what is expected, thereby reasserting our sense of freedom (Brehm & Brehm, 1981).

Committed individuals can sway the majority and make social history. Were this not so, communism would have remained an obscure theory, Christianity would be a small Middle Eastern sect, and Rosa Parks’ refusal to sit at the back of the bus would not have ignited the U.S. civil rights movement. Technological history, too, is often made by innovative minorities who overcome the majority’s resistance to change. To many, the railroad was a nonsensical idea; some farmers even feared that train noise would prevent hens from laying eggs. People derided Robert Fulton’s steamboat as “Fulton’s Folly.” As Fulton later said, “Never did a single encouraging remark, a bright hope, a warm wish, cross my path.” Much the same reaction greeted the printing press, the telegraph, the incandescent lamp, and the typewriter (Cantril & Bumstead, 1960).

The power of one or two individuals to sway majorities is *minority influence* (Moscovici, 1985). In studies of groups in which one or two individuals consistently express a controversial attitude or an unusual perceptual judgment, one finding repeatedly stands out: When you are the minority, you are far more likely to sway the majority if you hold firmly to your position and don’t waffle. This tactic won’t make you popular,

but it may make you influential, especially if your self-confidence stimulates others to consider *why* you react as you do. Even when a minority’s influence is not yet visible, people may privately develop sympathy for the minority position and rethink their views (Wood et al., 1994).

The bottom line: The powers of social influence are enormous, but so are the powers of the committed individual. For classical music, Mozart mattered. For drama, Shakespeare mattered. For world history, Hitler and Mao—and Gandhi and Mandela—mattered. Social forces matter. But individuals matter, too.

Gandhi As the life of Hindu nationalist and spiritual leader Mahatma Gandhi powerfully testifies, a consistent and persistent minority voice can sometimes sway the majority. Gandhi’s nonviolent appeals and fasts were instrumental in winning India’s independence from Britain in 1947.

RETRIEVAL PRACTICE

- What is social facilitation, and why is it more likely to occur with a well-learned task?
ANSWER: This improved performance in the presence of others is most likely to occur with a well-learned task, because the added arousal caused by an audience tends to strengthen the most likely response. This also predicts poorer performance on a difficult task in others' presence.
- People tend to exert less effort when working with a group than they would alone, which is called _____.
ANSWER: social loafing
- You are organizing a meeting of fiercely competitive political candidates. To add to the fun, friends have suggested handing out masks of the candidates' faces for supporters to wear. What phenomenon might these masks engage?
ANSWER: The anonymity provided by the masks, combined with the arousal of the contentious setting, might create *deindividuation* (lessened self-awareness and self-restraint).
- When like-minded groups discuss a topic, and the result is the strengthening of the prevailing opinion, this is called _____.
ANSWER: group polarization
- When a group's desire for harmony overrides its realistic analysis of other options, _____ has occurred.
ANSWER: groupthink

REVIEW Social Influence

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

- 13-3** What is automatic mimicry, and how do conformity experiments reveal the power of social influence?
- 13-4** What did Milgram's obedience experiments teach us about the power of social influence?
- 13-5** How is our behavior affected by the presence of others?
- 13-6** What are *group polarization* and *groupthink*, and how much power do we have as individuals?

TERMS AND CONCEPTS TO REMEMBER

RETRIEVAL PRACTICE Test yourself on these terms by trying to write down the definition before flipping back to the page number referenced to check your answer.

- conformity, p. 526
- normative social influence, p. 527
- informational social influence, p. 527
- social facilitation, p. 532
- cognitive dissonance theory, p. 523
- social loafing, p. 533
- deindividuation, p. 533
- group polarization, p. 534
- groupthink, p. 535

Antisocial Relations

Social psychology studies how we think about and influence one another, and also how we *relate* to one another. What causes us to harm, or to help, or to fall in love? How can we move a destructive conflict toward a just peace? In this section we ponder insights into *antisocial* relations gleaned by researchers who have studied prejudice and aggression.

Prejudice

- 13-7** What is *prejudice*? What are its social and emotional roots?

Prejudice means “prejudgment.” It is an unjustifiable and usually negative attitude toward a group—often a different cultural, ethnic, or gender group. Like all attitudes, prejudice is a three-part mixture of

prejudice an unjustifiable (and usually negative) attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action.

stereotype a generalized (sometimes accurate but often overgeneralized) belief about a group of people.

discrimination unjustifiable negative behavior toward a group and its members.

- *beliefs* (in this case, called **stereotypes**).
- *emotions* (for example, hostility or fear).
- predispositions to *action* (to discriminate).

Some stereotypes may be at least partly accurate. If you presume that young men tend to drive faster than elderly women, you may be right. People perceive Australians as having a rougher culture than the British, and in one analysis of millions of Facebook status updates, Australians did use more profanity (Kramer & Chung, 2011). But stereotypes can exaggerate—as when liberals and conservatives overestimate the extremity of the other’s views (Graham et al., 2012). Stereotypes can also bias behavior. To *believe* that obese people are gluttonous, and to *feel* dislike for an obese person, is to be *prejudiced*; prejudice is a negative *attitude*. To pass over all the obese people on a dating site, or to reject an obese person as a potential job candidate, is to discriminate; **discrimination** is a negative *behavior*.

How Prejudiced Are People?

Prejudice comes as both explicit (overt) and implicit (automatic) attitudes toward people of a particular ethnic group, gender, sexual orientation, or viewpoint. Some examples:

Explicit Ethnic Prejudice Americans’ expressed racial attitudes have changed dramatically in the last half-century. For example, support for all forms of racial contact, including interracial dating (**FIGURE 13.7**), has dramatically increased. “It’s all right for Blacks and Whites to date each other,” agreed 48 percent of Americans in 1987 and 86 percent in 2012 (Pew, 2012). “Marriage between Blacks and Whites” was approved by 4 percent of Americans in 1958 and 87 percent in 2013 (Newport, 2013).

Yet as *overt* prejudice wanes, *subtle* prejudice lingers. Despite increased verbal support for interracial marriage, many people admit that in socially intimate settings (dating, dancing, marrying) they, personally, would feel uncomfortable with someone of another race. And many people who say they would feel upset with someone making racist slurs actually, when hearing such racism, respond indifferently (Kawakami et al., 2009). Subtle prejudice may also take the form of “microaggressions,” such as race-related traffic stops or people’s reluctance to choose a train seat next to someone of a different race (Wang et al., 2011). A slew of recent experiments illustrates that prejudice can be not only subtle but also automatic and unconscious.

Nevertheless, overt prejudice persists. In the aftermath of the 9/11 terrorist attacks and the Iraq and Afghanistan wars, 4 in 10 Americans acknowledged “some feelings of prejudice against Muslims,” and about half of non-Muslims in Western Europe and the United States perceived Muslims as “violent” (Saad, 2006; Wike & Grim, 2007). With Americans feeling threatened by Arabs, and as opposition to Islamic mosques and immigration flared in 2010, one observer noted that “Muslims are one of the last

▼ **FIGURE 13.7**

Prejudice over time Over the last quarter-century, Americans have increasingly approved interracial dating, with each successive generation expressing more approval. (Data from Pew, 2012.)

minorities in the United States that it is still possible to demean openly” (Kristof, 2010; Lyons et al., 2010). Muslims worldwide reciprocated the negativity, with most in Jordan, Egypt, Turkey, and Britain seeing Westerners as “greedy” and “immoral.”

Implicit Prejudice As we have seen throughout this book, the human mind processes thoughts, memories, and attitudes on two different tracks. Sometimes that processing is *explicit*—on the radar screen of our awareness. To a much greater extent, it is *implicit*—below the radar, leaving us unaware of how our attitudes are influencing our behavior. Modern studies indicate that prejudice is often implicit, an automatic attitude—an unthinking knee-jerk response. Consider these findings:

Implicit racial associations Using Implicit Association Tests, researchers have demonstrated that even people who deny harboring racial prejudice may carry negative associations (Banaji & Greenwald, 2013). (By 2014, about 16 million people had taken the Implicit Association Test, as you can at www.implicit.harvard.edu.) For example, 9 in 10 White respondents took longer to identify pleasant words (such as *peace* and *paradise*) as “good” when presented with Black-sounding names (such as *Latisha* and *Darnell*) rather than with White-sounding names (such as *Katie* and *Ian*). Moreover, people who more quickly associate good things with White names or faces also are the quickest to perceive anger and apparent threat in Black faces (Hugenberg & Bodenhausen, 2003).

Although the test is useful for studying automatic prejudice, critics caution against using it to assess or label individuals (Oswald et al., 2013). Defenders counter that implicit biases predict behaviors ranging from simple acts of friendliness to the evaluation of work quality (Banaji & Greenwald, 2013). In the 2008 U.S. presidential election, implicit as well as explicit prejudice predicted voters’ support for candidate Barack Obama, whose election in turn served to reduce implicit prejudice (Bernstein et al., 2010; Payne et al., 2010; Stephens-Davidowitz, 2014).

 **LaunchPad** To take one version of the Implicit Associations Test, visit LaunchPad’s **Lab: Stereotyping**.

Unconscious patronization In one experiment, White university women assessed flawed student essays. When assessing essays supposedly written by White students, the women gave low evaluations, often with harsh comments, but not so when the essays were said to have been written by Black students (Harber, 1998). Did the evaluators calibrate their evaluations to their racial stereotypes, leading to less exacting standards and a patronizing attitude? In real-world evaluations, such low expectations and the resulting “inflated praise and insufficient criticism” could hinder minority student achievement, the researcher noted. (To preclude such bias, many teachers read essays while “blind” to their authors.)

Race-influenced perceptions Our expectations influence our perceptions. In 1999, Amadou Diallo was accosted as he approached his apartment house doorway by police officers looking for a rapist. When he pulled out his wallet, the officers, perceiving a gun, riddled his body with 19 bullets from 41 shots. Curious about this tragic killing of an unarmed, innocent man, two research teams reenacted the situation (Correll et al., 2002, 2007; Greenwald et al., 2003; Sadler et al., 2012). They asked viewers to press buttons quickly to “shoot” or not shoot men who suddenly appeared on screen. Some of the on-screen men held a gun. Others held a harmless object, such as a flashlight or bottle. People (both Blacks and Whites, in one study) more often shot Black men than White men who were holding the harmless objects. Priming people with a flashed Black rather than White face also made them more likely to misperceive a flashed tool as a gun (**FIGURE 13.8**). Fatigue, which diminishes one’s conscious control and increases automatic reactions, amplifies racial bias in decisions to shoot (Ma et al., 2013).

Does this automatic racial bias research help us understand the 2013 death of Trayvon Martin? As he walked alone to his father’s fiancée’s house

“Unhappily, the world has yet to learn how to live with diversity.”

Pope John Paul II,
Address to the United Nations, 1995

▼ **FIGURE 13.8**
Race primes perceptions In experiments by Keith Payne (2006), people viewed (1) a White or Black face, immediately followed by (2) a gun or hand tool, which was then followed by (3) a visual mask. Participants were more likely to misperceive a tool as a gun when it was preceded by a Black rather than White face.

▼ FIGURE 13.9

(1) Who do you like best?

(2) Which one placed an ad seeking “a special lady to love and cherish forever”? (See answers below.)

Research suggests that subtly feminized features convey a likable image, which people tend to associate more with committed dads than with promiscuous cads. Thus, 66 percent of the women picked computer-generated face (b) in response to both of these questions.

(a)

(b)

Professor Dave Perrett, St. Andrews University

in a gated Florida neighborhood, a suspicious resident started following him, leading to a confrontation and to Martin's being shot dead. Commentators wondered: Had Martin been an unarmed White teen, would he have been perceived and treated the same way?

Reflexive bodily responses Even people who consciously express little prejudice may give off telltale signals as their body responds selectively to another's race. Neuroscientists can detect these signals when people look at White and Black faces. The viewers' implicit prejudice may show up in facial-muscle responses and in the activation of their emotion-processing amygdala (Cunningham et al., 2004; Eberhardt, 2005; Stanley et al., 2008).

If your own gut-check reveals you sometimes have feelings you would rather not have about other people, remember this: It is what we *do* with our feelings that matters. By monitoring our feelings and actions, and by replacing old habits with new ones based on new friendships, we can work to free ourselves from prejudice.

Gender Prejudice Overt gender prejudice has also declined sharply. The one-third of Americans who in 1937 told Gallup pollsters that they would vote for a qualified woman whom their party nominated for president soared to 95 percent in 2012 (Gallup Brain, 2008; Jones, 2012). Nearly everyone now agrees that women and men should receive the same pay for the same job.

But gender prejudice and discrimination persist. Despite equality between the sexes in intelligence scores, people have tended to perceive their fathers as more intelligent than their mothers (Furnham & Wu, 2008). In Saudi Arabia, women have not been allowed to drive. In Western countries, we pay more to those (usually men) who care for our streets than to those (usually women) who care for our children. Worldwide, women are more likely to live in poverty (UN, 2010); they represent nearly two-thirds of illiterate adults (UNESCO, 2013); and 30 percent have experienced intimate partner violence (Devries et al., 2013).

Unwanted female infants are no longer left out on a hillside to die of exposure, as was the practice in ancient Greece. Yet natural female mortality and the normal male-to-female newborn ratio (105-to-100) hardly explain the world's estimated 163 million (say that number slowly) “missing women” (Hvistendahl, 2011). In many places, sons are valued more than daughters. In India, there are 3.5 times more Google searches asking how to conceive a boy than how to conceive a girl (Stephens-Davidowitz, 2014). With testing that enables sex-selective abortions, several Asian countries have experienced a shortfall in female births. Although China has declared that sex-selective abortions—gender genocide—are now a criminal offense, the country's newborn sex ratio has been 111 boys for every 100 girls, similar to India's 112 to 100 ratio (CIA, 2014). Some 95 percent of the children in Chinese orphanages have been girls (Webley, 2009). With under-age-20 males exceeding females by 32 million, many Chinese bachelors will be unable to find mates (Zhu et al., 2009). A shortage of women also contributes to increased crime, violence, prostitution, and trafficking of women (Brooks, 2012).

Studies have shown, however, that most people *feel* more positively about women in general than they do about men (Eagly, 1994; Haddock & Zanna, 1994). Worldwide, people see women as having some traits (such as nurturance, sensitivity, and less aggressiveness) that most people prefer (Glick et al., 2004; Swim, 1994). That may explain why women tend to like women more than men like men (Rudman & Goodwin, 2004). And perhaps that is also why people prefer slightly feminized computer-generated faces—men's and women's—to slightly masculinized faces. Researcher David Perrett and his colleagues (1998) have speculated that a slightly feminized male face connotes kindness, cooperativeness, and other traits of a good father. When the British Broadcasting Corporation invited 18,000 women to guess which of the men in **FIGURE 13.9** was most likely to place a personal ad seeking a “special lady to love and cherish forever,” which one do you think they picked?

Sexual Orientation Prejudice In most of the world, gay and lesbian people cannot openly and comfortably disclose who they are and whom they love (Katz-Wise & Hyde, 2012; United Nations, 2011). Dozens of countries have laws criminalizing same-sex relationships. But cultural variation is enormous—ranging from the 6 percent in Spain who say that “homosexuality is morally unacceptable” to 98 percent in Ghana (Pew, 2014). Anti-gay prejudice, though rapidly subsiding in Western countries, persists. Consider:

- In national surveys, 40 percent of LGBT Americans said it would be very or somewhat difficult for someone in their community “to live openly as gay or lesbian” (Jones, 2012). Thirty-nine percent reported having “been rejected by a friend or family member” because of their sexual orientation or gender identity. And 58 percent reported being “subject to slurs or jokes” (Pew, 2013).
- In the National School Climate Survey, 8 of 10 LGBT adolescents reported sexual orientation-related harassment in the prior year (GLSEN, 2012).

Do attitudes and practices that label, disparage, and discriminate against gay and lesbian people increase their risk of psychological disorder and ill health? In U.S. states without protections against LGBT hate crime and discrimination, gay and lesbian people experience substantially higher rates for depression and related disorders, even after controlling for income and education differences. In communities where anti-gay prejudice is high, so are gay and lesbian suicide and cardiovascular deaths. In sixteen states that banned same-sex marriage between 2001 and 2005, gays and lesbians (but not heterosexuals) experienced a 37 percent increase in depressive disorder rates, a 42 percent increase in alcohol use disorders, and a 248 percent increase in general anxiety disorders. Meanwhile, gays and lesbians in other states did not experience increased psychiatric disorders (Hatzenbuehler, 2014).

just-world phenomenon the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get.

Social Roots of Prejudice

Why does prejudice arise? Social inequalities and divisions are partly responsible.

Social Inequalities When some people have money, power, and prestige and others do not, the “haves” usually develop attitudes that justify things as they are. The **just-world phenomenon** reflects an idea we commonly teach our children—that good is rewarded and evil is punished. From this it is but a short leap to assume that those who succeed must be good and those who suffer must be bad. Such reasoning enables the rich to see both their own wealth and the poor’s misfortune as justly deserved. In an extreme case, slave “owners” perceived slaves as innately lazy, ignorant, and irresponsible—as having the very traits that justified enslaving them. Stereotypes rationalize inequalities.

Victims of discrimination may react with either self-blame or anger (Allport, 1954). Either reaction can feed prejudice through the classic *blame-the-victim* dynamic. Do the circumstances of poverty breed a higher crime rate? If so, that higher crime rate can be used to justify discrimination against those who live in poverty.

Us and Them: Ingroup and Outgroup We have inherited our Stone Age ancestors’ need to belong, to live and love in groups. There was safety in solidarity (those who didn’t band together left fewer descendants). Whether hunting, defending, or attacking, 10 hands were better than 2. Dividing the world into “us” and “them” entails racism and war, but it also provides the benefits of communal solidarity. Thus, we cheer for our groups, kill for them, die for them. Indeed, we define who we are partly in terms of our groups. Through our *social identities* we associate ourselves with certain groups and contrast ourselves with others (Dunham et al., 2013; Hogg, 1996,

The ingroup Scotland's famed "Tartan Army" soccer fans, shown here during a match against archrival England, share a social identity that defines "us" (the Scottish ingroup) and "them" (the English outgroup).

Mike Hewitt/Getty Images

Dave Coverly/Speed Bump

“For if [people were] to choose out of all the customs in the world [they would] end by preferring their own.”

Greek historian Herodotus, 440 B.C.E.

“If the Tiber reaches the walls, if the Nile does not rise to the fields, if the sky doesn't move or the Earth does, if there is famine, if there is plague, the cry is at once: ‘The Christians to the lion!’”

Tertullian, *Apologeticus*, 197 C.E.

2006; Turner, 1987, 2007). When Ian identifies himself as a man, an Aussie, a University of Sydney student, a Catholic, and a MacGregor, he knows who he is, and so do we.

Evolution prepared us, when encountering strangers, to make instant judgments: friend or foe? Those from our group, those who look like us, and also those who *sound* like us—with accents like our own—we instantly tend to like, from childhood onward (Gluszek & Dovidio, 2010; Kinzler et al., 2009). Mentally drawing a circle defines “us,” the **ingroup**. But the social definition of who you are also states who you are not. People outside that circle are “them,” the **outgroup**. An **ingroup bias**—a favoring of our own group—soon follows. Even arbitrarily creating us-them groups by tossing a coin creates this bias. In experiments, people have favored their own group when dividing any rewards (Tajfel, 1982; Wilder, 1981). Much discrimination involves not outgroup hostility but ingroup networking and mutual support, such as hiring a friend's child at the expense of other job candidates (Greenwald & Pettigrew, 2014).

The urge to distinguish enemies from friends predisposes prejudice against strangers (Whitley, 1999). To Greeks of the classical era, all non-Greeks were “barbarians.” In our own era, most children believe their school is better than all other schools in town. Many high school students form cliques—jocks, gamers, skaters, gangsters, freaks, geeks—and disparage those outside their own group. Even chimpanzees have been seen to wipe clean the spot where they were touched by a chimpanzee from another group (Goodall, 1986). They also display ingroup empathy by yawning more after seeing ingroup (rather than outgroup) members yawn (Campbell & de Waal, 2011).

Ingroup bias explains the cognitive power of political partisanship (Cooper, 2010; Douthat, 2010). In the United States in the late 1980s, most Democrats believed inflation had risen under Republican president Ronald Reagan (it had dropped). In 2010, most Republicans believed that taxes had increased under Democratic president Barack Obama (for most, they had decreased).

Emotional Roots of Prejudice

Prejudice springs not only from the divisions of society but also from the passions of the heart. **Scapegoat theory** notes that when things go wrong, finding someone to blame can provide a target for anger. Following the 9/11 terrorist attacks, some outraged people lashed out at innocent Arab-Americans. Others called for eliminating Saddam Hussein, the Iraqi leader whom Americans had been grudgingly tolerating. “Fear and anger create aggression, and aggression against citizens of different ethnicity or race creates racism and, in turn, new forms of terrorism,” noted Philip Zimbardo (2001). A decade after 9/11, anti-Muslim animosities still flared, with mosque burnings and efforts to block an Islamic community center near Ground Zero.

Evidence for the scapegoat theory of prejudice comes from high prejudice among economically frustrated people. And it comes from experiments in which a temporary frustration intensifies prejudice. Students who experience failure or are made to feel insecure often restore their self-esteem by disparaging a rival school or another person (Cialdini & Richardson, 1980; Crocker et al., 1987). To boost our own sense of status, it helps to denigrate others. That explains why a rival's misfortune sometimes provides a twinge of pleasure. (The German language has a word—*Schadenfreude*—for this secret joy that we sometimes take in another's failure.) By contrast, those made to feel loved and supported become more open to and accepting of others who differ (Mikulincer & Shaver, 2001).

Negative emotions nourish prejudice. When facing death, fearing threats, or experiencing frustration, people cling more tightly to their ingroup and their friends. As terrorism fear heightens patriotism, it also produces loathing and aggression toward “them”—those who threaten our world (Pyszczynski et al., 2002, 2008). The few individuals who lack fear and its associated activity in the emotion-processing amygdala—such as children with the genetic disorder Williams syndrome—also display a notable lack of racial stereotypes and prejudice (Santos et al., 2010).

Cognitive Roots of Prejudice

13-8 What are the cognitive roots of prejudice?

Prejudice springs from a culture's divisions, the heart's passions, and also from the mind's natural workings. Stereotyped beliefs are a by-product of how we cognitively simplify the world.

Forming Categories One way we simplify our world is to categorize. A chemist categorizes molecules as organic and inorganic. Therapists categorize psychological disorders. All of us categorize people by race, with mixed-race people often assigned to their minority identity. Despite his mixed-race background and being raised by a White mother and grandparents, President Barack Obama has been perceived by White Americans as Black. Researchers believe this happens because, after learning the features of a familiar racial group, the observer's selective attention is drawn to the distinctive features of the less-familiar minority. Jamin Halberstadt and his colleagues (2011) illustrated this learned-association effect by showing New Zealanders blended Chinese-Caucasian faces. Compared with participants of Chinese descent, European-descent New Zealanders more readily classified ambiguous faces as Chinese (see FIGURE 13.10).

When categorizing people into groups we often stereotype. We recognize how greatly *we* differ from other individuals in *our* groups. But we overestimate the homogeneity of other groups (we perceive *outgroup homogeneity*). “They”—the members of some other group—seem to look and act alike, while “we” are more diverse (Bothwell et al., 1989). To those in one ethnic group, members of another often seem more alike than they really are in attitudes, personality, and appearance. Our greater recognition

“The misfortunes of others are the taste of honey.”

Japanese saying

ingroup “us”—people with whom we share a common identity.

outgroup “them”—those perceived as different or apart from our ingroup.

ingroup bias the tendency to favor our own group.

scapegoat theory the theory that prejudice offers an outlet for anger by providing someone to blame.

▼ **FIGURE 13.10**
Categorizing mixed-race people When New Zealanders quickly classified 104 photos by race, those of European descent more often than those of Chinese descent classified the ambiguous middle two as Chinese (Halberstadt et al., 2011).

for individual own-race faces—called the **other-race effect** (also called the *cross-race effect* or *own-race bias*)—emerges during infancy, between 3 and 9 months of age (Anzures et al., 2013; Telzer et al., 2013). People’s superiority at recognizing faces of their own race is paralleled by an *own-age bias*—better recognition memory for faces of one’s own age group (Rhodes & Anastasi, 2012).

With effort and with experience, people get better at recognizing individual faces from another group (Hugenberg et al., 2010; Young et al., 2012). People of European descent, for example, more accurately identify individual African faces if they have watched a great deal of basketball on television, exposing them to many African-heritage faces (Li et al., 1996). And the longer Chinese people have resided in a Western country, the less they exhibit the other-race effect (Hancock & Rhodes, 2008).

Remembering Vivid Cases As we saw in Chapter 9, we often judge the frequency of events by instances that readily come to mind. In a classic experiment, researchers showed two groups of University of Oregon students lists containing information about 50 men (Rothbart et al., 1978). The first group’s list included 10 men arrested for *nonviolent* crimes, such as forgery. The second group’s list included 10 men arrested for *violent* crimes, such as assault. Later, both groups were asked how many men on their list had committed *any* sort of crime. The second group overestimated the number. Vivid—in this case, violent—cases are more readily available to our memory and feed our stereotypes (FIGURE 13.11).

▼ FIGURE 13.11

Vivid cases feed stereotypes The 9/11 Muslim terrorists created, in many minds, an exaggerated stereotype of Muslims as terrorism-prone. Actually, reported a U.S. National Research Council panel on terrorism, when offering this inexact illustration, most terrorists are not Muslim and “the vast majority of Islamic people have no connection with and do not sympathize with terrorism” (Smelser & Mitchell, 2002).

LaunchPad To review attribution research and experience a simulation of how stereotypes form, visit LaunchPad’s **PsychSim 6: Not My Type**. And for a 6.5-minute synopsis of the cognitive and social psychology of prejudice, visit LaunchPad’s **Video: Prejudice**.

Believing the World Is Just As we noted earlier, people often justify their prejudices by blaming victims. If the world is just, they assume, people must get what they deserve. As one German civilian is said to have remarked when visiting the Bergen-Belsen concentration camp shortly after World War II, “What terrible criminals these prisoners must have been to receive such treatment.”

Hindsight bias is also at work here (Carli & Leonard, 1989). Have you ever heard people say that rape victims, abused spouses, or people with AIDS got what they deserved? In some countries, such as Pakistan, rape victims have been sentenced to severe punishment for violating adultery prohibitions (Mydans, 2002). In one experiment illustrating the blame-the-victim phenomenon, people were given a detailed account of a date that ended with the woman being raped (Janoff-Bulman et al., 1985). They perceived the woman’s behavior as at least partly to blame, and in hindsight, they thought, “She should have known better.” Others, given the same account with the rape ending deleted, did not perceive the woman’s behavior as inviting rape. Hindsight bias promoted a blame-the-victim mentality among members of the first group. Blaming the victim also serves to reassure people that it couldn’t happen to them.

other-race effect the tendency to recall faces of one’s own race more accurately than faces of other races. Also called the *cross-race effect* and the *own-race bias*.

aggression any act intended to harm someone physically or emotionally.

People also have a basic tendency to justify their culture's social systems (Jost et al., 2009; Kay et al., 2009). We're inclined to see the way things are as the way they ought to be. This natural conservatism makes it difficult to legislate major social changes, such as health care or climate-change policies. Once such policies are in place, our "system justification" tends to preserve them.

RETRIEVAL PRACTICE

- When prejudiced judgment causes us to blame an undeserving person for a problem, that person is called a _____.

ANSWER: scapegoat

Aggression

13-9 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

Prejudice hurts, but aggression often hurts more. In psychology, **aggression** is any unwanted behavior intended to harm someone, whether done out of hostility or as a calculated means to an end. The assertive, persistent salesperson is not aggressive. Nor is the dentist who makes you wince with pain. But the person who passes along a vicious rumor about you, the person who bullies you in person or online, and the attacker who mugs you for your money are aggressive.

Aggressive behavior emerges from the interaction of biology and experience. For a gun to fire, the trigger must be pulled; with some people, as with hair-trigger guns, it doesn't take much to trip an explosion. Let's look first at some biological factors that influence our thresholds for aggressive behavior, then at the psychological factors that pull the trigger.

The Biology of Aggression

Aggression varies too widely from culture to culture, era to era, and person to person to be considered an unlearned instinct. But biology does *influence* aggression. We can look for biological influences at three levels—genetic, neural, and biochemical.

Genetic Influences Genes influence aggression. We know this because animals have been bred for aggressiveness—sometimes for sport, sometimes for research. The effect of genes also appears in human twin studies (Miles & Carey, 1997; Rowe et al., 1999). If one identical twin admits to "having a violent temper," the other twin will often independently admit the same. Fraternal twins are much less likely to respond similarly. Researchers continue to search for genetic markers in those who commit violent acts. One is already well known and is carried by half the human race: the Y chromosome. Another such marker is the *monoamine oxidase A (MAOA) gene*, which helps break down neurotransmitters such as dopamine and serotonin. Sometimes called the "warrior gene," people who have low MAOA gene expression tend to behave aggressively when provoked. In one experiment, low (compared with high) MAOA gene carriers gave more unpleasant hot sauce to someone who provoked them (McDermott et al., 2009).

Neural Influences There is no one spot in the brain that controls aggression. Aggression is a complex behavior, and it occurs in particular contexts. But animal and human brains have neural systems that, given provocation, will either inhibit or facilitate aggression (Denson, 2011; Moyer, 1983; Wilkowski et al., 2011). Consider:

- Researchers implanted a radio-controlled electrode in the brain of the domineering leader of a caged monkey colony. The electrode was in an area that, when stimulated, inhibits aggression. When researchers placed the control button for the electrode in the colony's cage, one small monkey learned to push it every time the boss became threatening.

Do guns in the home save or take more lives?

In the last 40 years in the United States, well over 1 million people—more than all deaths in all wars in American history—have been killed by firearms in nonwar settings. Compared with people of the same sex, race, age, and neighborhood, those who keep a gun in the home (ironically, often for protection) have been twice as likely to be murdered and three times as likely to commit suicide (Anglemeyer et al., 2014; Stroebe, 2013). States and countries with high gun ownership rates also tend to have high gun death rates (VPC, 2013).

"It's a guy thing."

The New Yorker Collection, 1995, D. Reilly from cartoonbank.com

- A neurosurgeon, seeking to diagnose a disorder, implanted an electrode in the amygdala of a mild-mannered woman. Because the brain has no sensory receptors, she was unable to feel the stimulation. But at the flick of a switch she snarled, “Take my blood pressure. Take it now,” then stood up and began to strike the doctor.
- Studies of violent criminals have revealed diminished activity in the frontal lobes, which play an important role in controlling impulses. If the frontal lobes are damaged, inactive, disconnected, or not yet fully mature, aggression may be more likely (Amen et al., 1996; Davidson et al., 2000; Raine, 2013).

Biochemical Influences Our genes engineer our individual nervous systems, which operate electrochemically. The hormone testosterone, for example, circulates in the bloodstream and influences the neural systems that control aggression. A raging bull becomes a gentle Ferdinand when castration reduces its testosterone level. Conversely, when injected with testosterone, gentle, castrated mice once again become aggressive.

Humans are less sensitive to hormonal changes. But as men age, their testosterone levels—and their aggressiveness—diminish. Hormonally charged, aggressive 17-year-olds mature into hormonally quieter and gentler 70-year-olds. Men more than women tend to have wide faces, a testosterone-linked trait, rather than roundish or long faces. And men’s facial width is a predictor of their aggressiveness and prejudicial attitudes (Carré et al., 2009; Hehman et al., 2013; Stirrat & Perrett, 2010). Women apparently pick up on this by *perceiving* men with higher facial width-to-height ratios as more dominant (Valentine et al., 2014).

High testosterone correlates with irritability, assertiveness, impulsiveness, and low tolerance for frustration—qualities that predispose somewhat more aggressive responses to provocation or competition for status (Dabbs et al., 2001b; McAndrew, 2009; Montoya et al., 2012). Among both teenage boys and adult men, high testosterone levels correlate with delinquency, hard drug use, and aggressive-bullying responses to frustration (Berman et al., 1993; Dabbs & Morris, 1990; Olweus et al., 1988). Drugs that sharply reduce testosterone levels subdue men’s aggressive tendencies.

Another drug that sometimes circulates in the bloodstream—alcohol—*unleashes* aggressive responses to frustration. Across police data, prison surveys, and experiments, aggression-prone people are more likely to drink, and to become violent when intoxicated (White et al., 1993). National crime data indicate that 73 percent of Russian homicides and 57 percent of U.S. homicides are alcohol-influenced (Landberg & Norström, 2011). Alcohol effects aggression both biologically and psychologically (Bushman, 1993; Ito et al., 1996; Taylor & Chermack, 1993). Just *thinking* you’ve imbibed alcohol can increase aggression (Bègue et al., 2009). But so, too, does unknowingly ingesting alcohol slipped into a drink. Unless people are distracted, alcohol tends to focus their attention on a provocation rather than on inhibitory cues (Giancola & Corman, 2007). Alcohol also inclines people to interpret ambiguous acts (such as a bump in a crowd) as provocations (Bègue et al., 2010).

“We could avoid two-thirds of all crime simply by putting all able-bodied young men in cryogenic sleep from the age of 12 through 28.”

David T. Lykken,
The Antisocial Personalities, 1995

A lean, mean fighting machine—the testosterone-laden female hyena The hyena’s unusual embryology pumps testosterone into female fetuses. The result is revved-up young female hyenas who seem born to fight.

Psychological and Social-Cultural Factors in Aggression

13-10 What psychological and social-cultural factors may trigger aggressive behavior?

Biological factors influence how easily aggression is triggered. But what psychological and social-cultural factors pull the trigger?

Aversive Events Suffering sometimes builds character. In laboratory experiments, however, those made miserable have often made others miserable (Berkowitz, 1983, 1989). This phenomenon is called the **frustration-aggression principle**: Frustration creates anger, which can spark aggression. One analysis of 27,667 hit-by-pitch Major League Baseball incidents between 1960 and 2004 revealed this link (Timmerman, 2007). Pitchers were most likely to hit batters when

- they had been frustrated by the previous batter hitting a home run.
- the current batter had hit a home run the last time at bat.
- a teammate had been hit by a pitch in the previous half inning.

Other aversive stimuli—hot temperatures, physical pain, personal insults, foul odors, cigarette smoke, crowding, and a host of others—can also evoke hostility. In laboratory experiments, when people get overheated, they think, feel, and act more aggressively. Simply thinking about words related to hot temperatures is enough to increase hostile thoughts (DeWall & Bushman, 2009). In baseball games, the number of hit batters rises with the temperature (Reifman et al., 1991; see **FIGURE 13.12**). In the wider world, violent crime and spousal abuse rates have been higher during hotter years, seasons, months, and days (Anderson et al., 1997). Other studies from archaeology, economics, geography, political science, and psychology converge in finding that throughout human history, higher temperatures have predicted increased individual violence, wars, and revolutions (Hsiang et al., 2013). From the available data, Craig Anderson and his colleagues (2000, 2011) have projected that, other things being equal, global warming of 4 degrees Fahrenheit (about 2 degrees Celsius) could induce tens of thousands of additional assaults and murders—and that’s before the added violence inducements from climate change-related drought, poverty, food insecurity, and migration.

Reinforcement, Modeling, and Self-Control Aggression may naturally follow aversive events, but learning can alter natural reactions. As Chapter 7 explained, we learn when our behavior is reinforced, and we learn by watching others.

In situations where experience has taught us that aggression pays, we are likely to act aggressively again. Children whose aggression has successfully intimidated other children may become bullies. Animals that have successfully fought to get food or mates become increasingly ferocious. To foster a kinder, gentler world we had best model and reward sensitivity and cooperation from an early age, perhaps by training parents to discipline without modeling violence.

Parent-training programs often advise parents to avoid modeling violence by screaming and hitting. Instead, parents should reinforce desirable behaviors and frame statements positively. (“When you finish loading the dishwasher you can go play,” rather than “If you don’t load the dishwasher, there’ll be no playing.”)

One *aggression-replacement program* worked with juvenile offenders and gang members and their parents. It taught both generations new ways to control anger, and more thoughtful approaches to moral reasoning (Goldstein et al., 1998). The result? The youths’ re-arrest rates dropped more than is typical.

Different cultures model, reinforce, and evoke different tendencies toward violence. For example, crime rates are higher and average happiness is lower in times and places

▼ FIGURE 13.12
Temperature and retaliation
 Richard Larrick and his colleagues (2011) looked for occurrences of batters hit by pitchers during 4,566,468 pitcher-batter matchups across 57,293 Major League Baseball games since 1952. The probability of a hit batter increased if one or more of the pitcher’s teammates had been hit, and also with temperature.

frustration-aggression principle the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression.

marked by a great disparity between rich and poor (Messias et al., 2011; Oishi et al., 2011; Wilkinson & Pickett, 2009). In the United States, cultures and families in which fathers are minimally involved also have high violence rates (Triandis, 1994). Even after controlling for parental education, race, income, and teen motherhood, American male youths from father-absent homes are incarcerated at twice the rate of their peers (Harper & McLanahan, 2004).

Violence can vary by culture within a country. Richard Nisbett and Dov Cohen (1996) analyzed violence among White Americans in southern towns settled by Scots-Irish herders whose tradition emphasized “manly honor,” the use of arms to protect one’s flock, and a history of coercive slavery. Compared with their White counterparts in New England towns settled by the more traditionally peaceful Puritan, Quaker, and Dutch farmer-artisans, the cultural descendants of those herders have had triple the homicide rates and were more supportive of physically punishing children, of warfare initiatives, and of uncontrolled gun ownership. “Culture-of-honor” states also have higher rates of students bringing weapons to school and of school shootings (Brown et al., 2009).

Media Models for Sexual Violence Parents are hardly the only aggression models. In the United States and elsewhere, TV, films, video games, and the Internet offer supersized portions of violence. Repeatedly viewing on-screen violence tends to make us less sensitive to cruelty (Montag et al., 2012). It also primes us to respond aggressively when provoked. And it teaches us **social scripts**—culturally provided mental files for how to act. When we find ourselves in new situations, uncertain how to behave, we rely on social scripts. After watching so many action films, adolescent boys may acquire a script that plays in their head when they face real-life conflicts. Challenged, they may “act like a man” by intimidating or eliminating the threat. More than 100 studies together confirm that people sometimes imitate what they’ve viewed. Watching risk-glorifying behaviors (dangerous driving, extreme sports, unprotected sex) increases viewers’ real-life risk-taking (Fischer et al., 2011).

Music lyrics also write social scripts. In experiments, German university men who listened to woman-hating song lyrics administered the most hot chili sauce to a woman. They also recalled more negative feelings and beliefs about women. Man-hating song lyrics had a similar effect on the aggressive behavior of women listeners (Fischer & Greitemeyer, 2006).

Sexual scripts depicted in pornographic films are often toxic. Researchers have found that repeatedly watching pornographic films, even nonviolent films, makes sexual aggression seem less serious (Harris, 1994). In one experiment, undergraduates viewed six brief, sexually explicit films each week for six weeks (Zillmann & Bryant, 1984). A control group viewed films with no sexual content during the same six-week period. Three weeks later, both groups read a newspaper report about a man convicted of raping a hitchhiker and were asked to suggest an appropriate prison term. Sentences recommended by those viewing the sexually explicit films were only half as long as the sentences recommended by the control group.

While nonviolent sexual content affects aggression-related sexual attitudes, violent sexual content can also increase men’s readiness to actually behave aggressively toward women. A statement by 21 social scientists noted, “Pornography that portrays sexual aggression as pleasurable for the victim increases the acceptance of the use of coercion in sexual relations” (Surgeon General, 1986). Contrary to much popular opinion, viewing such scenes does not provide an outlet for bottled-up impulses. Rather, “in laboratory studies measuring short-term effects, exposure to violent pornography increases punitive behavior toward women.”

To a lesser extent, nonviolent pornography can also influence aggression. One set of studies exploring pornography’s effects on aggression toward relationship partners found that pornography consumption predicted both self-reported aggression and

social script culturally modeled guide for how to act in various situations.

participants' willingness to administer laboratory noise blasts to their partner (Lambert et al., 2011). Abstaining from one's customary pornography consumption decreased aggression. Abstaining from a favorite food did not.

Do Violent Video Games Teach Social Scripts for Violence?

Experiments in North America, Western Europe, Singapore, and Japan indicate that playing positive games produces positive effects (Greitemeyer & Osswald, 2010, 2011; Prot et al., 2014). For example, playing *Lemmings*, where a goal is to help others, increases real-life helping. So, might a parallel effect occur after playing games that enact violence? Violent video games became an issue for public debate after teenagers in more than a dozen places seemed to mimic the carnage in the shooter games they had so often played (Anderson, 2004a, 2013).

In 2002, three young men in Michigan spent part of a night drinking beer and playing *Grand Theft Auto III*. Using simulated cars, they ran down pedestrians, then beat them with fists, leaving a bloody body behind (Kolker, 2002). These same young men then went out for a real drive. Spotting a 38-year-old man on a bicycle, they ran him down with their car, got out, stomped and punched him, and returned home to play the game some more. (The victim, a father of three, died six days later.)

Such violent mimicry causes some to wonder: What are the effects of actively role-playing aggression? Does it cause young people to become less sensitive to violence and more open to violent acts? Nearly 400 studies of 130,000 people offer an answer, report some researchers (Anderson et al., 2010). Video games can prime aggressive thoughts, decrease empathy, and increase aggression. University men who spend the most hours playing violent video games have also tended to be the most physically aggressive (Anderson & Dill, 2000). (For example, they more often acknowledged having hit or attacked someone else.) And people randomly assigned to play a game involving bloody murders with groaning victims (rather than to play nonviolent *Myst*) became more hostile. On a follow-up task, they were more likely to blast intense noise at a fellow student. Studies of young adolescents reveal that those who play a lot of violent video games become more aggressive and see the world as more hostile (Gentile, 2009; Hassin et al., 2013). Compared with nongaming kids, they get into more arguments and fights and earn poorer grades.

Ah, but is this merely because naturally hostile kids are drawn to such games? Apparently not. Comparisons of gamers and nongamers who scored low on hostility measures revealed a difference in the number of fights they reported. Almost 4 in 10 violent-game players had been in fights, compared with only 4 in 100 of the nongaming kids (Anderson, 2004a). Some researchers believe that, due partly to the more active participation and rewarded violence of game play, violent video games have even greater effects on aggressive behavior and cognition than do violent TV shows and movies (Anderson & Warburton, 2012).

Other researchers are unimpressed by such findings (Ferguson, 2013, 2014). They note that from 1996 to 2006, youth violence declined while video game sales increased, and argue that other factors—depression, family violence, peer influence—better predict aggression. Also, game-playing keeps people off the streets and out of trouble (Engelstätter et al., 2011). Moreover, some point out that avid game players are quick and sharp: They develop speedy reaction times and enhanced visual skills (Dye et al., 2009; Green et al., 2010). The focused fun of game playing can satisfy basic needs for a sense of competence, control, and social connection (Granic et al., 2014).

In 2011, a U.S. Supreme Court decision overturned a California state law that banned violent video game sales to children (modeled after the bans on sales of sexually explicit materials to children). The First Amendment's free speech guarantee protects even offensive games, said the court's majority, which was unpersuaded by the evidence of harm. So, the debate continues.

Coincidence or cause? In 2011, Norwegian Anders Behring Breivik bombed government buildings in Oslo, and then went to a youth camp where he shot and killed 69 people, mostly teens. As a player of first-person shooter games, Breivik stirred debate when he commented that “I see MW2 [*Modern Warfare 2*] more as a part of my training-simulation than anything else.” Did his violent game playing—and that of the 2012 mass murderer of Newtown, Connecticut’s first-grade children—contribute to the violence, or was it a merely coincidental association? To explore such questions, psychologists experiment.

* * *

To sum up, research reveals biological, psychological, and social-cultural influences on aggressive behavior. Complex behaviors, including violence, have many causes, making any single explanation an oversimplification. Asking what causes violence is therefore like asking what causes cancer.

Those who study the effects of asbestos exposure on cancer rates may remind us that asbestos is indeed a cancer cause, but it is only one among many. Like so much else, aggression is a biopsychosocial phenomenon (FIGURE 13.13).

A happy concluding note: Historical trends suggest that the world is becoming less violent over time (Pinker, 2011). That people vary across time and place reminds us that environments differ. Yesterday's plundering Vikings have become today's peace-promoting Scandinavians. Like all behavior, aggression arises from the interaction of persons and situations.

▼ FIGURE 13.13

Biopsychosocial understanding of aggression Because many factors contribute to aggressive behavior, there are many ways to change such behavior, including learning anger management and communication skills, and avoiding violent media and video games.

RETRIEVAL PRACTICE

- What biological, psychological, and social-cultural influences interact to produce aggressive behaviors?

ANSWER: Our biology (our genes, neural systems, and biochemistry—including testosterone and alcohol levels) influences our aggressive tendencies. Psychological factors (such as frustration, previous rewards for aggressive acts, and observation of others' aggression) can trigger any aggressive tendencies we may have. Social influences, such as exposure to violent media or being ostracized from a group, and cultural influences, such as whether we've grown up in a "culture of honor" or a father-absent home, can also affect our aggressive responses.

Prosocial Relations

Social psychologists focus not only on the dark side of social relationships, but also on the bright side, by studying *prosocial* behavior—behavior that intends to help or benefit someone. Our positive behaviors toward others are evident from explorations of attraction, altruism, and peacemaking.

mere exposure effect the phenomenon that repeated exposure to novel stimuli increases liking of them.

Attraction

Pause a moment and think about your relationships with two people—a close friend, and someone who has stirred your feelings of romantic love. What psychological chemistry binds us together in these special attachments? Social psychology suggests some answers.

The Psychology of Attraction

13-11 Why do we befriend or fall in love with some people but not others?

We endlessly wonder how we can win others' affection and what makes our own affections flourish or fade. Does familiarity breed contempt, or does it amplify affection? Do birds of a feather flock together, or do opposites attract? Is beauty only skin deep, or does physical attractiveness matter greatly? To explore these questions, let's consider three ingredients of our liking for one another: proximity, attractiveness, and similarity.

Proximity Before friendships become close, they must begin. *Proximity*—geographic nearness—is friendship's most powerful predictor. Proximity provides opportunities for aggression, but much more often it breeds liking. Study after study reveals that people are most inclined to like, and even to marry, those who live in the same neighborhood, who sit nearby in class, who work in the same office, who share the same parking lot, who eat in the same dining hall. Look around. Mating starts with meeting.

Proximity breeds liking partly because of the **mere exposure effect**. Repeated exposure to novel stimuli increases our liking for them. This applies to nonsense syllables, musical selections, geometric figures, Chinese characters, human faces, and the letters of our own name (Moreland & Zajonc, 1982; Nuttin, 1987; Zajonc, 2001). We are even somewhat more likely to marry someone whose first or last name resembles our own (Jones et al., 2004).

So, within certain limits, familiarity feeds fondness (Bornstein, 1989, 1999). Researchers demonstrated this by having four equally attractive women silently attend a 200-student class for zero, 5, 10, or 15 class sessions (Moreland & Beach, 1992). At the end of the course, students viewed slides of each woman and rated her attractiveness. The most attractive? The ones they'd seen most often. The phenomenon would come as no surprise to the young Taiwanese man who wrote more than 700 letters to his girlfriend, urging her to marry him. She did marry—the mail carrier (Steinberg, 1993).

Familiarity breeds acceptance

When this rare white penguin was born in the Sydney, Australia zoo, his tuxedoed peers ostracized him. Zookeepers thought they would need to dye him black to gain acceptance. But after three weeks of contact, the other penguins came to accept him.

Dan Kitwood/Getty Images

The mere exposure effect The mere exposure effect applies even to ourselves. Because the human face is not perfectly symmetrical, the face we see in the mirror is not the same face our friends see. Most of us prefer the familiar mirror image, while our friends like the reverse (Mita et al., 1977). The person German Chancellor Angela Merkel sees in the mirror each morning is shown at right, and that's the photo she would probably prefer. We might feel more comfortable with the reverse image (left), the one we see.

▼ FIGURE 13.14

I like the candidate who looks a bit like dear old me Jeremy Bailenson and his colleagues (2005) incorporated morphed features of voters' faces into the faces of 2004 U.S. presidential candidates George Bush and John Kerry. Without conscious awareness of their own incorporated features, the participants became more likely to favor the candidate whose face incorporated some of their own features.

No face is more familiar than your own. And that helps explain an interesting finding by Lisa DeBruine (2004): We like other people when their faces incorporate some morphed features of our own. When DeBruine (2002) had McMaster University students (both men and women) play a game with a supposed other player, they were more trusting and cooperative when the other person's image had some of their own facial features morphed into it. In me I trust. (See also FIGURE 13.14.)

For our ancestors, the mere exposure effect had survival value. What was familiar was generally safe and approachable. What was unfamiliar was more often dangerous and threatening. Evolution may therefore have hard-wired into us the tendency to bond with those who are familiar and to be wary of those who are unfamiliar (Zajonc, 1998). If so, gut-level prejudice against those who are culturally different could be a primitive, automatic emotional response (Devine et al., 2012). It's what we do with our knee-jerk prejudice that matters, say researchers. Do we let those feelings control our behavior? Or do we monitor our feelings and act in ways that reflect our conscious valuing of human equality?

Modern Matchmaking Those who have not found a romantic partner in their immediate proximity may cast a wider net by joining an online dating service. Published research on Internet matchmaking effectiveness is sparse. But this much seems well established: Some people, including occasional predators, dishonestly represent their age, attractiveness, occupation, or other details, and thus are not who they seem to be. Nevertheless, Katelyn McKenna and John Bargh and their colleagues have offered a surprising finding: Compared with relationships formed in person, Internet-formed friendships and romantic relationships are, on average, slightly more likely to last and be satisfying (Bargh et al., 2002, 2004; Cacioppo et al., 2013; McKenna et al., 2002). In one of their studies, people disclosed more, with less posturing, to those whom they met online. When conversing online with someone for 20 minutes, they felt more liking for that person than they did for someone they had met and talked with face to face. This was true even when (unknown to them) it was the same person! Internet friendships often feel as real and important to people as in-person relationships. Small wonder that the historic ways couples have met—at school, on the job, through family, or, especially, through friends—have been supplemented by a striking rise in couples who meet over the Internet. In a recent national survey of straight and gay/lesbian couples, nearly a quarter of heterosexual couples and some two-thirds of same-sex couples met online (Rosenfeld & Thomas, 2012; see FIGURE 13.15).

Speed dating pushes the search for romance into high gear. In a process pioneered by a matchmaking Jewish rabbi, people meet a succession of prospective partners, either in person or via webcam (Bower, 2009). After a 3- to 8-minute conversation, people move on to the next prospect. (In an in-person meeting, one partner—usually the woman—remains seated and the other circulates.) Those who want to meet again can arrange for future contact. For many participants, 4 minutes is enough time to

▼ **FIGURE 13.15**
Percent of heterosexual and same-sex couples who met online
 (Data from Rosenfeld & Thomas, 2012.)

form a feeling about a conversational partner and to register whether the partner likes them (Eastwick & Finkel, 2008a,b).

For researchers, speed dating offers a unique opportunity for studying influences on our first impressions of potential romantic partners. Among recent findings are these:

- Men are more transparent. Observers (male or female) watching videos of speed-dating encounters can read a man's level of romantic interest more accurately than a woman's (Place et al., 2009).
- Given more options, people's choices become more superficial. Meeting lots of potential partners leads people to focus on more easily assessed characteristics, such as height and weight (Lenton & Francesconi, 2010). This was true even when researchers controlled for time spent with each partner.
- Men wish for future contact with more of their speed dates; women tend to be more choosy. But this difference disappears if the conventional roles are reversed, so that men stay seated while women circulate (Finkel & Eastwick, 2009).

Physical Attractiveness Once proximity affords us contact, what most affects our first impressions? The person's sincerity? Intelligence? Personality? Hundreds of experiments reveal that it is something far more superficial: physical appearance. This finding is unnerving for those of us taught that “beauty is only skin deep” and “appearances can be deceiving.”

In one early study, researchers randomly matched new University of Minnesota students for a Welcome Week dance (Walster et al., 1966). Before the dance, the researchers gave each student a battery of personality and aptitude tests, and they rated each student's physical attractiveness. During the blind date, the couples danced and talked for more than two hours and then took a brief intermission to rate their dates. What determined whether they liked each other? Only one thing seemed to matter: appearance. Both the men and the women liked good-looking dates best. Women are more likely than men to say that another's looks don't affect them (Lippa, 2007). But studies show that a man's looks do affect women's behavior (Eastwick et al., 2014a,b). Speed-dating experiments confirm that attractiveness influences first impressions for both sexes (Belot & Francesconi, 2006; Finkel & Eastwick, 2008).

Physical attractiveness also predicts how often people date and how popular they feel. It affects initial impressions of people's personalities. We don't assume that attractive people are more compassionate, but research participants perceive them as healthier, happier, more sensitive, more successful, and more socially skilled (Eagly et al., 1991; Feingold, 1992; Hatfield & Sprecher, 1986). Attractive, well-dressed people have been more likely to make a favorable impression on potential employers, and they have

“I'd like to meet the algorithm that thought we'd be a good match.”

“Personal beauty is a greater recommendation than any letter of introduction.”

Aristotle, *Apothegems*, 330 B.C.E.

Percentage of Men and Women Who “Constantly Think About Their Looks”

	Men	Women
Canada	18%	20%
United States	17	27
Mexico	40	45
Venezuela	47	65

From Roper Starch survey, reported by McCool (1999).

Women have 91 percent of cosmetic procedures (ASPS, 2010). Women also recall others’ appearances better than do men (Mast & Hall, 2006).

Estimated length of human nose removed by U.S. plastic surgeons each year: 5469 feet (*Harper’s*, 2009).

tended to be more successful in their jobs (Cash & Janda, 1984; Langlois et al., 2000; Solomon, 1987). Income analyses show a penalty for plainness or obesity and a premium for beauty (Engemann & Owyang, 2005).

Even babies have preferred attractive over unattractive faces (Langlois et al., 1987). So do some blind people, as University of Birmingham professor John Hull (1990, p. 23) discovered after going blind. A colleague’s remarks on a woman’s beauty would strangely affect his feelings. He found this “deplorable. . . . What can it matter to me what sighted men think of women . . . yet I do care what sighted men think, and I do not seem able to throw off this prejudice.”

For those who find the importance of looks unfair and unenlightened, two findings may be reassuring. First, people’s attractiveness is surprisingly unrelated to their self-esteem and happiness (Diener et al., 1995; Major et al., 1984). Unless we have just compared ourselves with superattractive people, few of us (thanks, perhaps, to the mere exposure effect) view ourselves as unattractive (Thornton & Moore, 1993). Second, strikingly attractive people are sometimes suspicious that praise for their work may simply be a reaction to their looks. Less attractive people have been more likely to accept praise as sincere (Berscheid, 1981).

Beauty is also in the eye of the culture. Hoping to look attractive, people across the globe have pierced and tattooed their bodies, lengthened their necks, bound their feet, and dyed their hair. They have gorged themselves to achieve a full figure or liposuctioned fat to achieve a slim one, applied chemicals hoping to rid themselves of unwanted hair or to regrow wanted hair, strapped on leather garments to make their breasts seem smaller or surgically filled their breasts with silicone and worn Wonderbras to make them look bigger. Cultural ideals change over time. For women in North America, the ultra-thin ideal of the Roaring Twenties gave way to the soft, voluptuous Marilyn Monroe ideal of the 1950s, only to be replaced by today’s lean yet busty ideal.

Some aspects of attractiveness, however, do cross place and time (Cunningham et al., 2005; Langlois et al., 2000). By providing reproductive clues, bodies influence sexual attraction. As evolutionary psychologists explain (see Chapter 4), men in many cultures, from Australia to Zambia, judge women as more attractive if they have a youthful, fertile appearance, suggested by a low waist-to-hip ratio (Karremans et al., 2010; Perilloux et al., 2010; Platek & Singh, 2010). (I [DM] always thought my wife looked cute in her genes.) Women feel attracted to healthy-looking men, but especially—and more so when ovulating—to those who seem mature, dominant, masculine, and affluent (Gallup & Frederick, 2010; Gangestad et al., 2010). But faces matter, too. When people rate opposite-sex faces and bodies separately, the face tends to be the better predictor of overall physical attractiveness (Currie & Little, 2009; Peters et al., 2007).

In the eye of the beholder
 Conceptions of attractiveness vary by culture. Yet some adult physical features, such as a healthy appearance, seem attractive everywhere.

▼ **FIGURE 13.16**
Average is attractive Which of these faces offered by University of St. Andrews psychologist David Perrett (2002, 2010) is most attractive? Most people say it's the face on the right—of a nonexistent person that is the average composite of these 3 plus 57 other actual faces.

People everywhere also seem to prefer physical features—noses, legs, physiques—that are neither unusually large nor small. An averaged face is attractive (FIGURE 13.16). In one clever demonstration, researchers digitized the faces of up to 32 college students and used a computer to average them (Langlois & Roggman, 1990). Students judged the averaged, composite faces as more attractive than 96 percent of the individual faces. One reason is that averaged faces are symmetrical, and people with symmetrical faces and bodies are more sexually attractive (Rhodes et al., 1999; Singh, 1995; Thornhill & Gangestad, 1994). Merge either half of your face with its mirror image and your symmetrical new face would boost your attractiveness a notch.

Our feelings also influence our attractiveness judgments. Imagine two people. The first is honest, humorous, and polite. The second is rude, unfair, and abusive. Which one is more attractive? Most people perceive the person with the appealing traits as more physically attractive (Lewandowski et al., 2007). Those we like we find attractive.

Extreme makeover In affluent, beauty-conscious cultures, increasing numbers of people, such as this woman from the former American TV show *Extreme Makeover*, have turned to cosmetic surgery to improve their looks.

In a Rodgers and Hammerstein musical, Prince Charming asks Cinderella, “Do I love you because you’re beautiful, or are you beautiful because I love you?” Chances are it’s both. As we see our loved ones again and again, their physical imperfections grow less noticeable and their attractiveness grows more apparent (Beaman & Klentz, 1983; Gross & Crofton, 1977). Shakespeare said it in *A Midsummer Night’s Dream*: “Love looks not with the eyes, but with the mind.” Come to love someone and watch beauty grow.

Similarity So proximity has brought you into contact with someone, and your appearance has made an acceptable first impression. What influences whether you will become friends? As you get to know each other, will the chemistry be better if you are opposites or if you are alike?

It makes a good story—extremely different types liking or loving each other: Rat, Mole, and Badger in *The Wind in the Willows*, Frog and Toad in Arnold Lobel’s books, Edward and Bella in the *Twilight* series. The stories delight us by expressing what we seldom experience. In real life, opposites retract (Rosenbaum, 1986; Montoya &

“Play coy if you like, but no one can resist a perfectly symmetrical face.”

Herman Miller/
AP Photo

Beauty grows with mere exposure

Herman Miller, Inc.'s famed Aeron chair initially received high comfort ratings but abysmal beauty ratings. To some it looked like "lawn furniture" or "a giant prehistoric insect" (Gladwell, 2005). But then, with design awards, media visibility, and imitators, the ugly duckling became the company's best-selling chair ever and came to be seen as beautiful. With people, too, beauty lies partly in the beholder's eye and can grow with exposure.

Horton, 2013). Compared with randomly paired people, friends and couples are far more likely to share common attitudes, beliefs, and interests (and, for that matter, age, religion, race, education, intelligence, smoking behavior, and economic status).

Moreover, the more alike people are, the more their liking endures (Byrne, 1971). Journalist Walter Lippmann was right to suppose that love lasts "when the lovers love many things together, and not merely each other." Similarity breeds content. One app therefore matches people with potential dates based on their proximity, and on the similarity of their Facebook profiles.

Proximity, attractiveness, and similarity are not the only determinants of attraction. We also like those who like us. This is especially true when our self-image is low. When we believe someone likes us, we feel good and respond to them warmly, which leads them to like us even more (Curtis & Miller, 1986). To be liked is powerfully rewarding.

Indeed, all the findings we have considered so far can be explained by a simple *reward theory of attraction*: We will like those whose behavior is rewarding to us, including those who are both able and willing to help us achieve our goals (Montoya & Horton, 2014). When people live or work in close proximity to us, it requires less time and effort to develop the friendship and enjoy its benefits. When people are attractive, they are aesthetically pleasing, and associating with them can be socially rewarding. When people share our views, they reward us by validating our beliefs.

RETRIEVAL PRACTICE

- People tend to marry someone who lives or works nearby. This is an example of the _____ in action.

ANSWER: mere exposure effect

- How does being physically attractive influence others' perceptions?

ANSWER: Being physically attractive tends to elicit positive first impressions. People tend to assume that attractive people are healthier, happier, and more socially skilled than others are.

Romantic Love

13-12 How does romantic love typically change as time passes?

Sometimes people move quickly from initial impressions, to friendship, to the more intense, complex, and mysterious state of romantic love. If love endures, temporary *passionate love* will mellow into a lingering *companionate love* (Hatfield, 1988).

Passionate Love A key ingredient of **passionate love** is arousal. The two-factor theory of emotion (Chapter 12) can help us understand this intense positive absorption in another (Hatfield, 1988). That theory assumes that

- emotions have two ingredients—*physical arousal* plus *cognitive appraisal*.
- arousal from any source can enhance one emotion or another, depending on how we interpret and label the arousal.

Arousal can come from within, as we experience the excitement of a new relationship. But in tests of the two-factor theory, college men have been aroused by fright, by running in place, by viewing erotic materials, or by listening to humorous or repulsive monologues. They were then introduced to an attractive woman and asked to rate her (or their girlfriend). Unlike unaroused men, the stirred-up men attributed some of their arousal to the woman or girlfriend, and felt more attracted to her (Carducci et al., 1978; Dermer & Pyszczynski, 1978; White & Kight, 1984).

A sample experiment: Researchers studied people crossing two bridges above British Columbia's rocky Capilano River (Dutton & Aron, 1974, 1989). One, a swaying foot-bridge, was 230 feet above the rocks; the other was low and solid. The researchers had

Snapshots at jasonlove.com

Bill looked at Susan, Susan at Bill.
Suddenly death didn't seem like an option.
This was love at first sight.

an attractive young woman intercept men coming off each bridge, and ask their help in filling out a short questionnaire. She then offered her phone number in case they wanted to hear more about her project. Far more of those who had just crossed the high bridge—which left their hearts pounding—accepted the number and later called the woman. To be revved up and to associate some of that arousal with a desirable person is to feel the pull of passion. Adrenaline makes the heart grow fonder. And when sexual desire is supplemented by a growing attachment, the result is the passion of romantic love (Berscheid, 2010).

Companionate Love Although the desire and attachment of romantic love often endure, the intense absorption in the other, the thrill of the romance, the giddy “floating on a cloud” feelings typically fade. Does this mean the French are correct in saying that “love makes the time pass and time makes love pass”? Or can friendship and commitment keep a relationship going after the passion cools?

As love matures, it typically becomes a steadier **companionate love**—a deep, affectionate attachment (Hatfield, 1988). The flood of passion-facilitating hormones (testosterone, dopamine, adrenaline) subsides and another hormone, *oxytocin*, supports feelings of trust, calmness, and bonding with the mate. In the most satisfying of marriages, attraction and sexual desire endure, minus the obsession of early stage romance (Acevedo & Aron, 2009).

There may be adaptive wisdom to the shift from passion to attachment (Reis & Aron, 2008). Passionate love often produces children, whose survival is aided by the parents’ waning obsession with each other. Failure to appreciate passionate love’s limited half-life can doom a relationship (Berscheid et al., 1984). Indeed, recognizing the short duration of obsessive passionate love, some societies deem such feelings to be an irrational reason for marrying. Better, they say, to choose (or have someone choose for you) a partner with a compatible background and interests. Non-Western cultures, where people rate love as less important for marriage, do have lower divorce rates (Levine et al., 1995).

One key to a gratifying and enduring relationship is **equity**. When equity exists—when both partners receive in proportion to what they give—their chances for sustained and satisfying companionate love are good (Gray-Little & Burks, 1983; Van Yperen & Buunk, 1990). In one national survey, “sharing household chores” ranked third, after “faithfulness” and a “happy sexual relationship,” on a list of nine things people associated with successful marriages. “I like hugs. I like kisses. But what I really love is help with the dishes,” summarized the Pew Research Center (2007).

Equity’s importance extends beyond marriage. Mutually sharing one’s self and possessions, making decisions together, giving and getting emotional support, promoting and caring about each other’s welfare—all of these acts are at the core of every type of loving relationship (Sternberg & Grajek, 1984). It’s true for lovers, for parent and child, and for close friends.

Another vital ingredient of loving relationships is **self-disclosure**, the revealing of intimate details about ourselves—our likes and dislikes, our dreams and worries, our proud and shameful moments. “When I am with my friend,” noted the Roman statesman Seneca, “me thinks I am alone, and as much at liberty to speak anything as to think it.” Self-disclosure breeds liking, and liking breeds self-disclosure (Collins & Miller, 1994). As one person reveals a little, the other reciprocates, the first then reveals more, and on and on, as friends or lovers move to deeper levels of intimacy (Baumeister & Bratslavsky, 1999).

One experiment marched student pairs through 45 minutes of increasingly self-disclosing conversation—from “When did you last sing to yourself?” to “When did you last cry in front of another person? By yourself?” Others spent the time with small-talk questions, such as “What was your high school like?” (Aron et al., 1997). By the experiment’s end, those experiencing the escalating intimacy felt much closer to their conversation partner than did the small-talkers.

passionate love an aroused state of intense positive absorption in another, usually present at the beginning of a love relationship.

companionate love the deep affectionate attachment we feel for those with whom our lives are intertwined.

equity a condition in which people receive from a relationship in proportion to what they give to it.

self-disclosure the act of revealing intimate aspects of oneself to others.

“When two people are under the influence of the most violent, most insane, most delusive, and most transient of passions, they are required to swear that they will remain in that excited, abnormal, and exhausting condition continuously until death do them part.”

George Bernard Shaw, “Getting Married,” 1908

HI & LOIS

Love is an ancient thing In 2007, a 5000- to 6000-year-old “Romeo and Juliet” young couple was unearthed locked in embrace, near Rome.

Intimacy can also grow when we pause to ponder and write our feelings. Researchers invited one person from each of 86 dating couples to spend 20 minutes a day over three days either writing their deepest thoughts and feelings about the relationship or writing merely about their daily activities (Slatcher & Pennebaker, 2006). Those who wrote about their feelings expressed more emotion in their instant messages with their partners in the days following, and 77 percent were still dating three months later (compared with 52 percent of those who had written about their activities).

In addition to equity and self-disclosure, a third key to enduring love is *positive support*. While relationship conflicts are inevitable, we can ask ourselves whether our communications more often express sarcasm or support, scorn or sympathy, sneers or smiles. For unhappy couples, disagreements, criticisms, and put downs are routine. For happy couples in enduring relationships, positive interactions (compliments, touches, laughing) outnumber negative interactions (sarcasm, disapproval, insults) by at least 5 to 1 (Gottman, 2007; see also Sullivan et al., 2010).

In the mathematics of love, self-disclosing intimacy + mutually supportive equity = enduring companionate love.

RETRIEVAL PRACTICE

- How does the two-factor theory of emotion help explain *passionate love*?

ANSWER: Emotions consist of (1) physical arousal and (2) our interpretation of that arousal. Researchers have found that any source of arousal (running, fear, laughter) may be interpreted as passion in the presence of a desirable person.

- Two vital components for maintaining companionate love are _____ and _____.

ANSWERS: equity; self-disclosure

Altruism

13-13 When are people most—and least—likely to help?

Altruism is an unselfish concern for the welfare of others. In rescuing his jailer, Dirk Willems exemplified altruism. So also did Carl Wilkens and Paul Rusesabagina in Kigali, Rwanda. Wilkens, a Seventh Day Adventist missionary, was living there in 1994 with his family when militia from the Hutu ethnic group began to slaughter members of a minority ethnic group, the Tutsis. The U.S. government, church leaders, and friends all implored Wilkens to leave. He refused. After evacuating his family, and even after every other American had left Kigali, he alone stayed and contested the 800,000-person genocide. When the militia came to kill him and his Tutsi servants, Wilkens’ Hutu neighbors deterred them. Despite repeated death threats, he spent his days running roadblocks to take food and water to orphanages and to negotiate, plead, and bully his way through the bloodshed, saving lives time and again. “It just seemed the right thing to do,” he later explained (Kristof, 2004).

altruism unselfish regard for the welfare of others.

Elsewhere in Kigali, Rusesabagina, a Hutu married to a Tutsi and the acting manager of a luxury hotel, was sheltering more than 1200 terrified Tutsis and moderate Hutus. When international peacekeepers abandoned the city and hostile militia threatened his guests in the “Hotel Rwanda” (as it came to be called in a 2004 movie), the courageous Rusesabagina began cashing in past favors. He bribed the militia and telephoned influential people abroad to exert pressure on local authorities, thereby sparing the lives of the hotel’s occupants from the surrounding chaos. Both Wilkens and Rusesabagina were displaying altruism, an unselfish regard for the welfare of others.

Altruism became a major concern of social psychologists after an especially vile act. On March 13, 1964, a stalker repeatedly stabbed Kitty Genovese, then raped her as she lay dying outside her Queens, New York, apartment at 3:30 A.M. “Oh, my God, he stabbed me!” Genovese screamed into the early morning stillness. “Please help me!” Windows opened and lights went on as neighbors heard her screams. Her attacker fled and then returned to stab and rape her again. Not until he had fled for good did anyone so much as call the police, at 3:50 A.M.

Bystander Intervention

Reflecting on initial reports of the Genovese murder and other such tragedies, most commentators were outraged by the bystanders’ apparent “apathy” and “indifference.” Rather than blaming the onlookers, social psychologists John Darley and Bibb Latané (1968b) attributed their inaction to an important situational factor—the presence of others. Given certain circumstances, they suspected, most of us might behave similarly. To paraphrase the French writer Voltaire, we all are guilty of the good we did not do.

After staging emergencies under various conditions, Darley and Latané assembled their findings into a decision scheme: We will help only if the situation enables us first to *notice* the incident, then to *interpret* it as an emergency, and finally to *assume responsibility* for helping (FIGURE 13.17). At each step, the presence of others can turn us away from the path that leads to helping.

Darley and Latané reached their conclusions after interpreting the results of a series of experiments. For example, as students in different laboratory rooms talked over an intercom, the experimenters simulated an emergency. Each student was in a separate cubicle, and only the person whose microphone was switched on could be heard. When his turn came, one student (an accomplice of the experimenters) made sounds as though he were having an epileptic seizure, and he called for help (Darley & Latané, 1968a).

How did the others react? As FIGURE 13.18 on the next page shows, those who believed only they could hear the victim—and therefore thought they alone were

Finbarr O'Reilly/Reuters/Landov

Why do genocides occur?

An estimated 800,000 people died during the Rwandan Genocide of 1994, when Hutu groups carried out mass killings of Tutsis. Social psychology research helps us understand some of the factors motivating genocides. We tend to categorize our world into us and them, and, when threatened, to feel greater animosity toward outside groups.

“Probably no single incident has caused social psychologists to pay as much attention to an aspect of social behavior as Kitty Genovese’s murder.”

R. Lance Shotland (1984)

▼ **FIGURE 13.17**
The decision-making process for bystander intervention Before helping, one must first notice an emergency, then correctly interpret it, and then feel responsible. (Adapted from Darley & Latané, 1968b.)

▼ FIGURE 13.18

Responses to a simulated physical emergency

When people thought they alone heard the calls for help from a person they believed to be having an epileptic seizure, they usually helped. But when they thought four others were also hearing the calls, fewer than a third responded. (Data from Darley & Latané, 1968a.)

LaunchPad For a review of research on emergency helping, visit LaunchPad's **Concept Practice: When Will People Help Others?**

responsible for helping him—usually went to his aid. Students who thought others could also hear the victim's cries were more likely to do nothing. When more people shared responsibility for helping—when there was a *diffusion of responsibility*—any single listener was less likely to help.

Hundreds of additional experiments have confirmed this **bystander effect**. For example, researchers and their assistants took 1497 elevator rides in three cities and “accidentally” dropped coins or pencils in front of 4813 fellow passengers (Latané & Darley, 1968). When alone with the person in need, 40 percent helped; in the presence of 5 other bystanders, only 20 percent helped.

Observations of behavior in thousands of these situations—relaying an emergency phone call, aiding a stranded motorist, donating blood, picking up dropped books, contributing money, giving time—show that the *best* odds of our helping someone occur when

- the person appears to need and deserve help.
- the person is in some way similar to us.
- the person is a woman.
- we have just observed someone else being helpful.
- we are not in a hurry.
- we are in a small town or rural area.
- we are feeling guilty.
- we are focused on others and not preoccupied.
- we are in a good mood.

This last result, that happy people are helpful people, is one of the most consistent findings in all of psychology. As poet Robert Browning (1868) observed, “Oh, make us happy and you make us good!” It doesn't matter how we are cheered. Whether by being made to feel successful and intelligent, by thinking happy thoughts, by finding money, or even by receiving a posthypnotic suggestion, we become more generous and more eager to help (Carlson et al., 1988). And given a feeling of elevation after witnessing or learning of someone else's self-giving deed, our helping will become even more pronounced (Schnall et al., 2010).

So happiness breeds helpfulness. But it's also true that helpfulness breeds happiness. Making charitable donations activates brain areas associated with reward (Harbaugh et al., 2007). That helps explain a curious finding: People who give money away are happier than those who spend it almost entirely on themselves. In a survey of more than 200,000 people worldwide, people in both rich and poor countries were happier with their lives if they had donated to a charity in the last month (Aknin et al., 2013). Just reflecting on a time when one spent money on others provides most people with a mood boost. And in one experiment, researchers gave people an envelope with cash and instructions either to spend it on themselves or to spend it on others (Dunn et al., 2008, 2013). Which group was happiest at the day's end? It was, indeed, those assigned to the spend-it-on-others condition.

bystander effect the tendency for any given bystander to be less likely to give aid if other bystanders are present.

social exchange theory the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs.

reciprocity norm an expectation that people will help, not hurt, those who have helped them.

social-responsibility norm an expectation that people will help those needing their help.

RETRIEVAL PRACTICE

- Why didn't anybody help Kitty Genovese? What social psychology principle did this incident illustrate?

ANSWER: In the presence of others, an individual is less likely to notice a situation, correctly interpret it as an emergency, and take responsibility for offering help. The Kitty Genovese case demonstrated this bystander effect, as each witness assumed many others were also aware of the event.

The Norms for Helping

13-14 How do social exchange theory and social norms explain helping behavior?

Why do we help? One widely held view is that self-interest underlies all human interactions, that our constant goal is to maximize rewards and minimize costs. Accountants call it *cost-benefit analysis*. Philosophers call it *utilitarianism*. Social psychologists call it **social exchange theory**. If you are pondering whether to donate blood, you may weigh the costs of doing so (time, discomfort, and anxiety) against the benefits (reduced guilt, social approval, and good feelings). If the rewards exceed the costs, you will help.

Others believe that we help because we have been socialized to do so, through norms that prescribe how we *ought* to behave. Through socialization, we learn the **reciprocity norm**: the expectation that we should return help, not harm, to those who have helped us. In our relations with others of similar status, the reciprocity norm compels us to give (in favors, gifts, or social invitations) about as much as we receive. In one experiment, people who were generously treated also became more likely to be generous to a stranger—to “pay it forward” (Tsvetkova & Macy, 2014).

The reciprocity norm kicked in after Dave Tally, a Tempe, Arizona homeless man, found \$3300 in a backpack that an Arizona State University student had misplaced on his way to buy a used car (Lacey, 2010). Instead of using the cash for much-needed bike repairs, food, and shelter, Tally turned the backpack in to the social service agency where he volunteered. To reciprocate Tally's help, the student thanked him with a reward. Hearing about Tally's self-giving deeds, dozens of others also sent him money and job offers.

We also learn a **social-responsibility norm**: that we should help those who need our help—young children and others who cannot give as much as they receive—even if the costs outweigh the benefits. Construction worker Wesley Autrey exemplified the social-responsibility norm on January 2, 2007. He and his 6- and 4-year-old daughters were awaiting a New York City subway train when, before them, a man collapsed in a seizure, got up, then stumbled to the platform's edge and fell onto the tracks. With train headlights approaching, “I had to make a split-second decision,” Autrey later recalled (Buckley, 2007). His decision, as his girls looked on in horror, was to leap from the platform, push the man off the tracks and into a foot-deep space between them, and lay atop him. As the train screeched to a halt, five cars traveled just above his head, leaving grease on his knit cap. When Autrey cried out, “I've got two daughters up there. Let them know their father is okay,” onlookers erupted into applause.

People who attend weekly religious services often are admonished to practice the social-responsibility norm, and sometimes they do. In American surveys, they have reported twice as many volunteer hours spent helping the poor and infirm, compared with those who rarely or never attend religious services (Hodgkinson & Weitzman, 1992; Independent Sector, 2002). Between 2006 and 2008, Gallup polls sampled more than 300,000 people across 140 countries, comparing the “highly religious” (who said religion was important to them and who had attended a religious service in the prior week) to those less religious. The highly religious, despite being poorer, were about 50 percent more likely to report having “donated money to a charity in the last month” and to have volunteered time to an organization (Pelham & Crabtree, 2008).

Subway hero Wesley Autrey:

“I don't feel like I did something spectacular; I just saw someone who needed help.” Five years later, a similar situation occurred when another man was shoved onto subway tracks—and no one helped (Nocera, 2012). Social psychologists have wondered: Under what conditions will people help?

Nick Brooks/Newsday/AP Photo

conflict a perceived incompatibility of actions, goals, or ideas.

social trap a situation in which the conflicting parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior.

Peacemaking

We live in surprising times. With astonishing speed, recent democratic movements swept away totalitarian rule in Eastern European and Arab countries, and hopes for a new world order displaced the Cold War chill. And yet, the twenty-first century began with terrorist acts and war. *Every day*, the world has continued to spend almost \$5 billion for arms and armies—money that could have been used for housing, nutrition, education, and health care. Knowing that wars begin in human minds, psychologists have wondered: What in the human mind causes destructive conflict? How might the perceived threats of social diversity be replaced by a spirit of cooperation?

Elements of Conflict

13-15 How do social traps and mirror-image perceptions fuel social conflict?

To a social psychologist, a **conflict** is a perceived incompatibility of actions, goals, or ideas. The elements of conflict are much the same, whether we are speaking of nations at war, cultural groups feuding within a society, or partners sparring in a relationship. In each situation, people become enmeshed in potentially destructive processes that can produce unwanted results. Among these processes are social traps and distorted perceptions.

Social Traps In some situations, we support our collective well-being by pursuing our personal interests. As capitalist Adam Smith wrote in *The Wealth of Nations* (1776), “It is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their own interest.” In other situations, we harm our collective well-being by pursuing our personal interests. Such situations are **social traps**.

Consider the simple game matrix in **FIGURE 13.19**, which is similar to those used in experiments with thousands of people. Both sides can win or both can lose, depending on the players’ individual choices. Pretend you are Person 1, and that you and Person 2 will each receive the amount shown after you separately choose either A or B. (You might invite someone to look at the matrix with you and take the role of Person 2.) Which do you choose—A or B?

You and Person 2 are caught in a dilemma. If you both choose A, you both benefit, making \$5 each. Neither of you benefits if you both choose B, for neither of you makes anything. Nevertheless, on any single trial you serve your own interests if you choose B: You can’t lose, and you might make \$10. But the same is true for the other person. Hence, the social trap: As long as you both pursue your own immediate best interest and choose B, you will both end up with nothing—the typical result—when you could have made \$5.

▼ **FIGURE 13.19**
Social-trap game matrix By pursuing our self-interest and not trusting others, we can end up losers. To illustrate this, imagine playing the game on the right. The light-orange triangles show the outcomes for Person 1, which depend on the choices made by both players. If you were Person 1, would you choose A or B? (This game is called a *non-zero-sum* game because the outcomes need not add up to zero; both sides can win or both can lose.)

		Person 1	
		Choose A	Choose B
Person 2	Choose A	Optimal outcome +\$5 +\$5	+\$10 -\$5
	Choose B	-\$5 +\$10	Probable outcome 0 0

Many real-life situations similarly pit our individual interests against our communal well-being. Individual whalers reasoned that the few whales they took would not threaten the species and that if they didn't take them, others would anyway. The result: Some species of whales became endangered. Ditto for the buffalo hunters of yesterday and the elephant-tusk poachers of today. Individual car owners and home owners reason, "Hybrid and electric cars are more expensive and not as cool as the model I'd like to buy. Besides, the fuel that I burn in my one car doesn't noticeably add to the greenhouse gases." When enough people reason similarly, the collective result threatens disaster—climate change, rising seas, and more extreme weather.

Jeff J. Mitchell/Getty Images

Not in my ocean! Many people support alternative energy sources, including wind turbines. But proposals to construct wind farms in real-world places elicit less support. Potential wind turbines in the Highlands and off the coast of Scotland produced heated debate over the benefits of clean energy versus the costs of altering treasured views.

Social traps challenge us to reconcile our right to pursue our personal well-being with our responsibility for the well-being of all. Psychologists have therefore explored ways to convince people to cooperate for their mutual betterment—through agreed-upon *regulations*, through better *communication*, and through promoting *awareness* of our responsibilities toward community, nation, and the whole of humanity (Dawes, 1980; Linder, 1982; Sato, 1987). Given effective regulations, communication, and awareness, people more often cooperate, whether playing a laboratory game or the real game of life.

Enemy Perceptions Psychologists have noted that those in conflict have a curious tendency to form diabolical images of one another. These distorted images are, ironically, so similar that we call them **mirror-image perceptions**: As we see “them”—as untrustworthy, with evil intentions—so “they” see us. Each demonizes the other.

Mirror-image perceptions can often feed a vicious cycle of hostility. If Juan believes Maria is annoyed with him, he may snub her, causing her to act in ways that justify his perception. As with individuals, so with countries. Perceptions can become **self-fulfilling prophecies**. They may confirm themselves by influencing the other country to react in ways that seem to justify them.

Individuals and nations alike tend to see their own actions as responses to provocation, not as the causes of what happens next. Perceiving themselves as returning tit for tat, they often hit back harder, as University College London volunteers did in one experiment (Shergill et al., 2003). Their task: After feeling pressure on their own finger, they were to use a mechanical device to press on another volunteer's finger. Although told to reciprocate with the same amount of pressure, they typically responded with about 40 percent more force than they had just experienced. Despite seeking only to respond in kind, their touches soon escalated to hard presses, much as when each child after a fight claims that “I just poked him, but he hit me harder.”

Mirror-image perceptions feed similar cycles of hostility on the world stage. To most people, torture seems more justified when done by “us” rather than “them” (Tarrant et al., 2012). In American media reports, Muslims who kill have been portrayed as fanatical, hateful terrorists, while an American who allegedly killed 16 Afghans was portrayed as struggling financially, drunk, brain-injured, and stressed out from marriage problems, four tours of duty, and a friend's having had his leg blown off (Greenwald, 2012).

mirror-image perceptions mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive.

self-fulfilling prophecy a belief that leads to its own fulfillment.

The point is not that truth must lie midway between two such views; one may be more accurate. The point is that enemy perceptions often form mirror images. Moreover, as enemies change, so do perceptions. In American minds and media, the “blood-thirsty, cruel, treacherous” Japanese of World War II later became our “intelligent, hardworking, self-disciplined, resourceful allies” (Gallup, 1972).

RETRIEVAL PRACTICE

- Why do sports fans tend to feel a sense of satisfaction when their archrival team loses? Why do such feelings, in other settings, make conflict resolution more challenging?

ANSWER: Sports fans may feel a part of an *ingroup* that sets itself apart from an *outgroup* (fans of the archrival team). Ingroup bias tends to develop, leading to prejudice and the view that the outgroup “deserves” misfortune. So, the archrival team’s loss may seem justified. In conflicts, this kind of thinking is problematic, especially when each side in the conflict develops *mirror-image perceptions* of the other (distorted, negative images that are ironically similar).

Promoting Peace

13-16 How can we transform feelings of prejudice, aggression, and conflict into attitudes that promote peace?

How can we make peace? Can contact, cooperation, communication, and conciliation transform the antagonisms fed by prejudice and conflicts into attitudes that promote peace? Research indicates that, in some cases, they can.

Contact Does it help to put two conflicting parties into close contact? It depends. Negative contact increases *disliking* (Barlow et al., 2012). But positive contact—especially non-competitive contact between parties of equal status, such as fellow store clerks—typically helps. Initially prejudiced co-workers of different races have, in such circumstances, usually come to accept one another. This finding is confirmed by a statistical digest of more than 500 studies of face-to-face contact between majority people and outgroups (such as ethnic minorities, the elderly, and those with disabilities). Among the quarter-million people studied across 38 nations, contact has been correlated with, or in experimental studies has led to, more positive attitudes (Al Ramiah & Hewstone, 2013; Pettigrew & Tropp, 2011). Some examples:

- With cross-racial contact, South Africans’ interracial attitudes have moved “into closer alignment” (Dixon et al., 2007; Finchilescu & Tredoux, 2010). In South Africa, as elsewhere, the contact effect is somewhat less for lower-status ethnic groups’ views of higher-status groups (Durrheim & Dixon, 2010; Gibson & Claassen, 2010). Still, cross-group friendships have led to more positive attitudes by South African Coloured teens toward minority White teens (Swart et al., 2011).
- Heterosexuals’ attitudes toward gay people are influenced not only by *what* they know but also by *whom* they know (Collier et al., 2012; Smith et al., 2009). In surveys, the reason people most often give for becoming more supportive of same-sex marriage is “having friends, family, or acquaintances who are gay or lesbian” (Pew, 2013).
- Friendly contact, say between Blacks and Whites as roommates, improves attitudes toward others of the different race, and even toward other racial outgroups (Gaither & Sommers, 2013; Tausch et al., 2010).
- Even indirect contact with an outgroup member (via story reading or through a friend who has an outgroup friend) has reduced prejudice (Cameron & Rutland, 2006; Pettigrew et al., 2007).

However, contact is not always enough. In most desegregated schools, ethnic groups resegregate themselves in lunchrooms, in classrooms, and elsewhere on school grounds

(Alexander & Tredoux, 2010; Clack et al., 2005; Schofield, 1986). People in each group often think that they would welcome more contact with the other group, but they assume the other group does not reciprocate the wish (Richeson & Shelton, 2007). “I don’t reach out to them, because I don’t want to be rebuffed; they don’t reach out to me, because they’re just not interested.” When such mirror-image misperceptions are corrected, friendships may form and prejudices melt.

Cooperation To see if enemies could overcome their differences, researcher Muzafer Sherif (1966) set a conflict in motion. He separated 22 Oklahoma City boys into two separate camp areas. Then he had the two groups compete for prizes in a series of activities. Before long, each group became intensely proud of itself and hostile to the other group’s “sneaky,” “smart-alecky stinkers.” Food wars broke out. Cabins were ransacked. Fistfights had to be broken up by camp counselors. Brought together, the two groups avoided each other, except to taunt and threaten. Little did they know that within a few days, they would be friends.

Sherif accomplished this by giving them **superordinate goals**—shared goals that could be achieved only through cooperation. When he arranged for the camp water supply to “fail,” all 22 boys had to work together to restore the water. To rent a movie in those pre-Netflix days, they all had to pool their resources. To move a stalled truck, the boys needed to combine their strength, pulling and pushing together. Having used isolation and competition to make strangers into enemies, Sherif used shared predicaments and goals to turn enemies into friends. What reduced conflict was not mere contact, but *cooperative* contact.

A shared predicament likewise had a powerfully unifying effect in the weeks after the 9/11 attacks. Patriotism soared as Americans felt “we” were under attack. Gallup-surveyed approval of “our President” shot up from 51 percent the week before the attack to a highest-ever 90 percent level 10 days after (Newport, 2002). In chat groups and everyday speech, even the word *we* (relative to *I*) surged in the immediate aftermath (Pennebaker, 2002). Children and youth exposed to war, and minority group members facing rejection or discrimination, likewise develop strong ingroup identification (Bauer et al., 2014; Ramos et al., 2012).

At such times, cooperation can lead people to define a new, inclusive group that dissolves their former subgroups (Dovidio & Gaertner, 1999). To accomplish this, you might seat members of two groups not on opposite sides, but alternately around a table. Give them a new, shared name. Have them work together. Then watch “us” and “them” become “we.” After 9/11, one 18-year-old New Jersey man described this shift in his

“You cannot shake hands with a clenched fist.”

Indira Gandhi, 1971

Shawn Baldwin/FILE/AP Photo

Kofi Annan: “Most of us have overlapping identities which unite us with very different groups. We *can* love what we are, without hating what—and who—we are *not*. We can thrive in our own tradition, even as we learn from others” (Nobel lecture, 2001).

superordinate goals shared goals that override differences among people and require their cooperation.

own social identity: “I just thought of myself as Black. But now I feel like I’m an American, more than ever” (Sengupta, 2001). In a real experiment, White Americans who read a newspaper article about a terrorist threat against all Americans subsequently expressed reduced prejudice against Black Americans (Dovidio et al., 2004).

If cooperative contact between rival group members encourages positive attitudes, might this principle bring people together in multicultural schools? Could interracial friendships replace competitive classroom situations with cooperative ones? Could cooperative learning maintain or even enhance student achievement? Experiments with adolescents from 11 countries confirm that, in each case, the answer is *Yes* (Roseth et al., 2008). In the classroom as in the sports arena, members of interracial groups who work together on projects typically come to feel friendly toward one another. Knowing this, thousands of teachers have made interracial cooperative learning part of their classroom experience.

The power of cooperative activity to make friends of former enemies has led psychologists to urge increased international exchange and cooperation. Some experiments have found that just imagining the shared threat of global climate change reduces international hostilities (Pyszczynski et al., 2012). From adjacent Brazilian tribes to European countries, formerly conflicting groups have managed to build interconnections, interdependence, and a shared social identity as they seek common goals (Fry, 2012). As we engage in mutually beneficial trade, as we work to protect our common destiny on this fragile planet, and as we become more aware that our hopes and fears are shared, we can transform misperceptions that feed conflict into feelings of solidarity based on common interests.

Communication When real-life conflicts become intense, a third-party mediator—a marriage counselor, labor mediator, diplomat, community volunteer—may facilitate much-needed communication (Rubin et al., 1994). Mediators help each party to voice its viewpoint and to understand the other’s needs and goals. If successful, mediators can replace a competitive *win-lose* orientation with a cooperative *win-win* orientation that leads to a mutually beneficial resolution. A classic example: Two friends, after quarreling over an orange, agreed to split it. One squeezed his half for juice. The other used the peel from her half to flavor a cake. If only the two had communicated their motives to one another, they could have hit on the win-win solution of one having all the juice, the other all the peel.

Superordinate goals override differences Cooperative efforts to achieve shared goals are an effective way to break down social barriers.

Grant Hindsley/AP Photo

Conciliation Understanding and cooperative resolution are most needed, yet least likely, in times of anger or crisis (Bodenhausen et al., 1994; Tetlock, 1988). When conflicts intensify, images become more stereotyped, judgments more rigid, and communication more difficult, or even impossible. Each party is likely to threaten, coerce, or retaliate. In the weeks before the 1990 Gulf War, the first President George Bush threatened, in the full glare of publicity, to “kick Saddam’s ass.” Saddam Hussein communicated in kind, threatening to make Americans “swim in their own blood.”

Under such conditions, is there an alternative to war or surrender? Social psychologist Charles Osgood (1962, 1980) advocated a strategy of *Graduated and Reciprocated Initiatives in Tension-Reduction*, nicknamed **GRIT**. In applying GRIT, one side first announces its recognition of mutual interests and its intent to reduce tensions. It then initiates one or more small, conciliatory acts. Without weakening one’s retaliatory capability, this modest beginning opens the door for reciprocity by the other party. Should the enemy respond with hostility, one reciprocates in kind. But so, too, with any conciliatory response.

In laboratory experiments, small conciliatory gestures—a smile, a touch, a word of apology—have allowed both parties to begin edging down the tension ladder to a safer rung where communication and mutual understanding can begin (Lindsfold et al., 1978, 1988). In a real-world international conflict, U.S. President John F. Kennedy’s gesture of stopping atmospheric nuclear tests began a series of reciprocated conciliatory acts that culminated in the 1963 atmospheric test-ban treaty.

As working toward shared goals reminds us, we are more alike than different. Civilization advances not by conflict and cultural isolation, but by tapping the knowledge, the skills, and the arts that are each culture’s legacy to the whole human race. Thanks to cultural sharing, every modern society is enriched by a cultural mix (Sowell, 1991). We have China to thank for paper and printing and for the magnetic compass that opened the great explorations. We have Egypt to thank for trigonometry. We have the Islamic world and India’s Hindus to thank for our Arabic numerals. While celebrating and claiming these diverse cultural legacies, we can also welcome the enrichment of today’s social diversity. We can view ourselves as instruments in a human orchestra. And we—including this book’s worldwide readers—can therefore each affirm our own culture’s heritage while building bridges of communication, understanding, and cooperation across our cultural traditions.

“To begin with, I would like to express my sincere thanks and deep appreciation for the opportunity to meet with you. While there are still profound differences between us, I think the very fact of my presence here today is a major breakthrough.”

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

- 13-11** Why do we befriend or fall in love with some people but not others?
- 13-12** How does romantic love typically change as time passes?
- 13-13** When are people most—and least—likely to help?
- 13-14** How do social exchange theory and social norms explain helping behavior?
- 13-15** How do social traps and mirror-image perceptions fuel social conflict?
- 13-16** How can we transform feelings of prejudice, aggression, and conflict into attitudes that promote peace?

TERMS AND CONCEPTS TO REMEMBER

RETRIEVAL PRACTICE Test yourself on these terms by trying to write down the definition before flipping back to check your answers.

- mere exposure effect, p. 551
- passionate love, p. 556
- companionate love, p. 557
- equity, p. 557
- self-disclosure, p. 557
- altruism, p. 558
- bystander effect, p. 560
- social exchange theory, p. 561
- reciprocity norm, p. 561
- social-responsibility norm, p. 561
- conflict, p. 562
- social trap, p. 562
- mirror-image perceptions, p. 563
- self-fulfilling prophecy, p. 563
- superordinate goals, p. 565
- GRIT, p. 567

TEST YOURSELF

SOCIAL PSYCHOLOGY

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Social Thinking

1. If we encounter a person who appears to be high on drugs, and we make the fundamental attribution error, we will probably attribute the person's behavior to
 - a. moral weakness or an addictive personality.
 - b. peer pressure.
 - c. the easy availability of drugs on city streets.
 - d. society's acceptance of drug use.
2. Celebrity endorsements in advertising often lead consumers to purchase products through _____ (central/peripheral) route persuasion.
3. We tend to agree to a larger request more readily if we have already agreed to a small request. This tendency is called the _____ - _____ - _____ - _____ phenomenon.

4. Jamal's therapist has suggested that Jamal should "act as if" he is confident, even though he feels insecure and shy. Which social psychological theory would best support this suggestion, and what might the therapist be hoping to achieve?

Social Influence

5. Researchers have found that a person is most likely to conform to a group if
 - a. the group members have diverse opinions.
 - b. the person feels competent and secure.
 - c. the person admires the group's status.
 - d. no one else will observe the person's behavior.
6. In Milgram's experiments, the rate of compliance was highest when
 - a. the "learner" was at a distance from the "teacher."
 - b. the "learner" was close at hand.
 - c. other "teachers" refused to go along with the experimenter.
 - d. the "teacher" disliked the "learner."

7. Dr. Huang, a popular music professor, delivers fascinating lectures on music history but gets nervous and makes mistakes when describing exam statistics in front of the class. Why does his performance vary by task?
8. In a group situation that fosters arousal and anonymity, a person sometimes loses self-consciousness and self-control. This phenomenon is called _____.
9. Sharing our opinions with like-minded others tends to strengthen our views, a phenomenon referred to as _____.

Antisocial Relations

10. Prejudice toward a group involves negative feelings, a tendency to discriminate, and overly generalized beliefs referred to as _____.
11. If several well-publicized murders are committed by members of a particular group, we may tend to react with fear and suspicion toward all members of that group. What psychological principle can help explain this reaction?
12. The other-race effect occurs when we assume that other groups are _____ (more/less) homogeneous than our own group.
13. Evidence of a biochemical influence on aggression is the finding that
 - a. aggressive behavior varies widely from culture to culture.
 - b. animals can be bred for aggressiveness.
 - c. stimulation of an area of the brain's limbic system produces aggressive behavior.
 - d. a higher-than-average level of the hormone testosterone is associated with violent behavior in males.
14. Studies show that parents of delinquent young people tend to use beatings to enforce discipline. This suggests that aggression can be
 - a. learned through direct rewards.
 - b. triggered by exposure to violent media.
 - c. learned through observation of aggressive models.
 - d. caused by hormone changes at puberty.

15. A conference of social scientists studying the effects of pornography unanimously agreed that violent pornography
 - a. has little effect on most viewers.
 - b. is the primary cause of reported and unreported rapes.
 - c. leads viewers to be more accepting of coercion in sexual relations.
 - d. has no effect, other than short-term arousal and entertainment.
16. The aspect of pornographic films that most directly influences men's aggression toward women seems to be the
 - a. length of the film.
 - b. eroticism portrayed.
 - c. depictions of sexual violence.
 - d. attractiveness of the actors.

Prosocial Relations

17. The more familiar a stimulus becomes, the more we tend to like it. This exemplifies the _____ effect.
18. A happy couple celebrating their 50th wedding anniversary is likely to experience deep _____ love, even though their _____ love has probably decreased over the years.
19. After vigorous exercise, you meet an attractive person, and you are suddenly seized by romantic feelings for that person. This response supports the two-factor theory of emotion, which assumes that emotions, such as passionate love, consist of physical arousal plus
 - a. a reward.
 - b. proximity.
 - c. companionate love.
 - d. our interpretation of that arousal.
20. The bystander effect states that a particular bystander is less likely to give aid if
 - a. the victim is similar to the bystander in appearance.
 - b. no one else is present.
 - c. other people are present.
 - d. the incident occurs in a deserted or rural area.
21. Our enemies often have many of the same negative impressions of us as we have of them. This exemplifies the concept of _____ - _____ perceptions.
22. One way of resolving conflicts and fostering cooperation is by giving rival groups shared goals that help them override their differences. These are called _____ goals.

Find answers to these questions in Appendix D, in the back of the book.

Introduction to Personality and Psychodynamic Theories

Humanistic Theories and Trait Theories

Social-Cognitive Theories and the Self

PERSONALITY

.....

Lady Gaga dazzles millions with her unique musical arrangements, tantalizing outfits, and provocative performance theatrics. In shows around the world, Lady Gaga's most predictable feature is her unpredictability. She has worn a meat dress to an award show, performed in a plastic bubble dress, and caused President Barack Obama to experience her, in her 16-inch heels, as "a little intimidating."

Lady Gaga's fans and critics alike can depend on her openness to new experiences and the energy she gets from the spotlight. But they can also rely on her careful, painstaking dedication to her music and performances. She describes herself in high school as "very dedicated, very studious, and very disciplined." Now, in adulthood, she shows similar self-discipline: "I'm very detailed—every minute of the show has got to be perfect."

Lady Gaga exhibits distinctive and enduring ways of thinking, feeling, and behaving. Earlier chapters focused on the ways we all develop, perceive, learn, remember, think, and feel. This chapter emphasizes what makes us unique—our *personality*.

Much of this book deals with personality. Earlier chapters considered biological influences on personality; personality development across the life span; how personality relates to learning, motivation, emotion, and health; and social influences on personality. The next chapter will study disorders of personality. This chapter focuses on personality itself—what it is and how researchers study it.

We begin with two historically important theories of personality: Sigmund Freud's *psychoanalytic theory* and the *humanistic* approach. These sweeping perspectives on human nature laid the foundation for later personality theorists and for what this chapter presents next: newer scientific explorations of personality.

Today's personality researchers study the basic dimensions of personality, and the interaction of persons and environments. They also study self-esteem, self-serving bias, and cultural influences on our concept of self—that sense of "Who I am." And they study the unconscious mind—with findings that probably would have surprised even Freud.

Sigmund Freud (1856–1939) “I was the only worker in a new field.”

Introduction to Personality and Psychodynamic Theories

What Is Personality?

14-1 What historically significant and current theories inform our understanding of personality?

OUR **PERSONALITY** IS OUR CHARACTERISTIC pattern of thinking, feeling, and acting. Two historically significant theories have become part of our cultural legacy. Sigmund Freud’s psychoanalytic theory proposed that childhood sexuality and unconscious motivations influence personality. The humanistic approach focused on our inner capacities for growth and self-fulfillment. Later theorists built upon these two broad perspectives. Trait theories, for example, examine characteristic patterns of behavior (*traits*). *Social-cognitive theories* explore the interaction between people’s traits (including their thinking) and their social context. Let’s begin with psychodynamic theories.

Psychodynamic Theories

Psychodynamic theories of personality view human behavior as a dynamic interaction between the conscious mind and the unconscious mind, including associated motives and conflicts. These theories are descended from Freud’s **psychoanalysis**—his theory of personality and the associated treatment techniques. Freud was the first to focus clinical attention on our unconscious mind.

Freud’s Psychoanalytic Perspective: Exploring the Unconscious

14-2 How did Sigmund Freud’s treatment of psychological disorders lead to his view of the unconscious mind?

Ask 100 people on the street to name a notable deceased psychologist, suggested Keith Stanovich (1996, p. 1), and “Freud would be the winner hands down.” In the popular mind, he is to psychology what Elvis Presley is to rock music. Freud’s influence not only lingers in psychiatry and clinical psychology, but also in literary and film interpretation. Almost 9 in 10 American college courses that reference psychoanalysis have been outside of psychology departments (Cohen, 2007). His early twentieth-century concepts penetrate our twenty-first-century language. Without realizing their source, we may speak of *ego*, *repression*, *projection*, *complex* (as in “inferiority complex”), *sibling rivalry*, *Freudian slips*, and *fixation*. So, who was Freud, and what did he teach?

Like all of us, Sigmund Freud was a product of his times. His Victorian era was a time of tremendous discovery and scientific advancement, but it is also known today as a time of sexual repression and male dominance. Men’s and women’s roles were clearly defined, with male superiority assumed and only male sexuality generally acknowledged (discreetly).

Long before entering the University of Vienna in 1873, young Freud showed signs of independence and brilliance. He so loved reading plays, poetry, and philosophy that he once ran up a bookstore debt beyond his means. As a teen he often took his evening meal in his tiny bedroom in order to lose no time from his studies. After medical school he set up a private practice specializing in nervous disorders. Before long, however, he faced patients whose disorders made no neurological sense. A patient might have lost all feeling in a hand—yet there is no sensory nerve that, if damaged, would numb the entire hand and nothing else. Freud’s search for a cause for such disorders set his mind running in a direction destined to change human self-understanding.

personality an individual’s characteristic pattern of thinking, feeling, and acting.

psychodynamic theories view personality with a focus on the unconscious and the importance of childhood experiences.

psychoanalysis Freud’s theory of personality that attributes thoughts and actions to unconscious motives and conflicts; the techniques used in treating psychological disorders by seeking to expose and interpret unconscious tensions.

“The female . . . acknowledges the fact of her castration, and with it, too, the superiority of the male and her own inferiority; but she rebels against this unwelcome state of affairs.”

Sigmund Freud, *Female Sexuality*, 1931

Might some neurological disorders have psychological causes? Observing patients led Freud to his “discovery” of the **unconscious**. He speculated that lost feeling in one’s hand might be caused by a fear of touching one’s genitals; that unexplained blindness or deafness might be caused by not wanting to see or hear something that aroused intense anxiety. After some early unsuccessful trials with hypnosis, Freud turned to **free association**, in which he told the patient to relax and say whatever came to mind, no matter how embarrassing or trivial. He assumed that a line of mental dominoes had fallen from his patients’ distant past to their troubled present. Free association, he believed, would allow him to retrace that line, following a chain of thought leading into the patient’s unconscious. There, painful unconscious memories, often from childhood, could be retrieved and released.

Basic to Freud’s theory was his belief that the mind is mostly hidden (**FIGURE 14.1**). Our *conscious* awareness is like the part of an iceberg that floats above the surface. Beneath our awareness is the larger *unconscious* mind, with its thoughts, wishes, feelings, and memories. Some of these thoughts we store temporarily in a *preconscious* area, from which we can retrieve them into conscious awareness. Of greater interest to Freud was the mass of unacceptable passions and thoughts that he believed we *repress*, or forcibly block from our consciousness because they would be too unsettling to acknowledge. Freud believed that without our awareness, these troublesome feelings and ideas powerfully influence us, sometimes gaining expression in disguised forms—the work we choose, the beliefs we hold, our daily habits, our troubling symptoms.

Personality Structure

14-3 What was Freud’s view of personality?

In Freud’s view, human personality—including its emotions and strivings—arises from a conflict between impulse and restraint—between our aggressive, pleasure-seeking biological urges and our internalized social controls over these urges. Freud believed personality arises from our efforts to resolve this basic conflict—to express these impulses in ways that bring satisfaction without also bringing guilt or punishment. To understand the mind’s dynamics during this conflict, Freud proposed three interacting systems: the *id*, *ego*, and *superego* (Figure 14.1).

The *id*’s unconscious psychic energy constantly strives to satisfy basic drives to survive, reproduce, and aggress. The *id* operates on the *pleasure principle*: It seeks

unconscious according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware.

free association in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing.

id a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The *id* operates on the *pleasure principle*, demanding immediate gratification.

▼ **FIGURE 14.1**

Freud’s idea of the mind’s structure

Psychologists have used an iceberg image to illustrate Freud’s idea that the mind is mostly hidden beneath the conscious surface. Note that the *id* is totally unconscious, but *ego* and *superego* operate both consciously and unconsciously. Unlike the parts of a frozen iceberg, however, the *id*, *ego*, and *superego* interact.

“Fifty is plenty.” “Hundred and fifty.”

The ego struggles to reconcile the demands of superego and id, said Freud.

“I heard that as soon as we become aware of our sexual impulses, whatever they are, we’ll have to hide them.”

ego the largely conscious, “executive” part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id’s desires in ways that will realistically bring pleasure rather than pain.

superego the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations.

psychosexual stages the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id’s pleasure-seeking energies focus on distinct erogenous zones.

Oedipus [ED-uh-puss] **complex** according to Freud, a boy’s sexual desires toward his mother and feelings of jealousy and hatred for the rival father.

immediate gratification. To envision an id-dominated person, think of a newborn infant crying out for satisfaction, caring nothing for the outside world’s conditions and demands. Or think of people with a present rather than future time perspective—those who heavily use tobacco, alcohol, and other drugs, and would sooner party now than sacrifice today’s pleasure for future success and happiness (Keough et al., 1999).

As the **ego** develops, the young child responds to the real world. The ego, operating on the *reality principle*, seeks to gratify the id’s impulses in realistic ways that will bring long-term pleasure. (Imagine what would happen if, lacking an ego, we expressed all our unrestrained sexual or aggressive impulses.) The ego contains our partly conscious perceptions, thoughts, judgments, and memories.

Around age 4 or 5, Freud theorized, a child’s ego recognizes the demands of the newly emerging **superego**, the voice of our moral compass (conscience) that forces the ego to consider not only the real but the *ideal*. The superego focuses on how we *ought* to behave. It strives for perfection, judging actions and producing positive feelings of pride or negative feelings of guilt. Someone with an exceptionally strong superego may be virtuous yet guilt ridden; another with a weak superego may be outrageously self-indulgent and remorseless.

Because the superego’s demands often oppose the id’s, the ego struggles to reconcile the two. It is the personality “executive,” mediating among the impulsive demands of the id, the restraining demands of the superego, and the real-life demands of the external world. If chaste Jane feels sexually attracted to John, she may satisfy both id and superego by joining a volunteer organization that John attends regularly.

Personality Development

14-4 What developmental stages did Freud propose?

Analysis of his patients’ histories convinced Freud that personality forms during life’s first few years. He concluded that children pass through a series of **psychosexual stages**, during which the id’s pleasure-seeking energies focus on distinct pleasure-sensitive areas of the body called *erogenous zones* (TABLE 14.1). Each stage offers its own challenges, which Freud saw as conflicting tendencies.

Freud believed that during the *phallic stage*, for example, boys seek genital stimulation. They also develop both unconscious sexual desires for their mother and jealousy and hatred for their father, whom they consider a rival. Given these feelings, he thought, boys also experience guilt and a lurking fear of punishment, perhaps by castration, from their father. Freud called this collection of feelings the **Oedipus complex** after the Greek legend of Oedipus, who unknowingly killed his father and married his mother. Some psychoanalysts in Freud’s era believed that girls experienced a parallel *Electra complex*.

▼ TABLE 14.1
Freud’s Psychosexual Stages

Stage	Focus
Oral (0–18 months)	Pleasure centers on the mouth—sucking, biting, chewing
Anal (18–36 months)	Pleasure focuses on bowel and bladder elimination; coping with demands for control
Phallic (3–6 years)	Pleasure zone is the genitals; coping with incestuous sexual feelings
Latency (6 to puberty)	A phase of dormant sexual feelings
Genital (puberty on)	Maturation of sexual interests

Children eventually cope with the threatening feelings, said Freud, by repressing them and by identifying with (trying to become like) the rival parent. It's as though something inside the child decides, "If you can't beat 'em [the same-sex parent], join 'em." Through this **identification** process, children's superegos gain strength as they incorporate many of their parents' values. Freud believed that identification with the same-sex parent provided what psychologists now call our *gender identity*—our sense of being male, female, or a combination of the two. Freud presumed that our early childhood relations—especially with our parents and caregivers—influence our developing identity, personality, and frailties.

In Freud's view, conflicts unresolved during earlier psychosexual stages could surface as maladaptive behavior in the adult years. At any point in the oral, anal, or phallic stages, strong conflict could lock, or **fixate**, the person's pleasure-seeking energies in that stage. A person who had been either orally overindulged or deprived (perhaps by abrupt, early weaning) might fixate at the oral stage. This orally fixated adult could exhibit either passive dependence (like that of a nursing infant) or an exaggerated denial of this dependence (by acting tough or uttering biting sarcasm). Or the person might continue to seek oral gratification by smoking or excessive eating. In such ways, Freud suggested, the twig of personality is bent at an early age.

Freud's ideas of sexuality were controversial in his own time. "Freud was called a dirty-minded pansexualist and Viennese libertine," noted historian of psychology Morton Hunt (2007, p. 211). Today, Freud's ideas of Oedipal conflict and castration anxiety are disputed even by psychodynamic theorists and therapists (Shedler, 2010b). Yet we still teach them as part of the history of Western ideas.

Defense Mechanisms

14-5 How did Freud think people defended themselves against anxiety?

Anxiety, said Freud, is the price we pay for civilization. As members of social groups, we must control our sexual and aggressive impulses, not act them out. But sometimes the ego fears losing control of this inner id-superego war. The presumed result is a dark cloud of unfocused anxiety that leaves us feeling unsettled but unsure why.

Freud proposed that the ego protects itself with **defense mechanisms**—tactics that reduce or redirect anxiety by distorting reality. For Freud, *all defense mechanisms function indirectly and unconsciously*. Just as the body unconsciously defends itself against disease, so also does the ego unconsciously defend itself against anxiety. For example, **repression** banishes anxiety-arousing wishes and feelings from consciousness. According to Freud, *repression underlies all the other defense mechanisms*. However, because repression is often incomplete, repressed urges may appear as symbols in dreams or as slips of the tongue in casual conversation.

Freud believed he could glimpse the unconscious seeping through when a financially stressed patient, not wanting any large pills, said, "Please do not give me any bills, because I cannot swallow them." (Similarly, sex-related slips of the tongue increased among men sitting next to an attractive young woman rather than a middle-aged man [saying *bare shoulders* instead of *share boulders*; Motley & Baars, 1979].) Freud also viewed jokes as expressions of repressed sexual and aggressive tendencies, and dreams as the "royal road to the unconscious." The remembered content of dreams (their *manifest content*) he believed to be a censored expression of the dreamer's unconscious wishes (the dream's *latent content*). In his dream analyses, Freud searched for patients' inner conflicts.

TABLE 14.2 on the next page describes a sampling of six other well-known defense mechanisms.

"Oh, for goodness' sake! Smoke!"

"Good morning, beheaded—uh, I mean beloved."

"I remember your name perfectly but I just can't think of your face."

Oxford professor W. A. Spooner (1844–1930) famous for his linguistic flip-flops (*spoonerisms*). Spooner rebuked one student for "fighting a liar in the quadrangle" and another who "hissed my mystery lecture," adding "You have tasted two worms."

identification the process by which, according to Freud, children incorporate their parents' values into their developing superegos.

fixation according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved.

defense mechanisms in psychoanalytic theory, the ego's protective methods of reducing anxiety by unconsciously distorting reality.

repression in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories.

▼ TABLE 14.2
Six Defense Mechanisms

Freud believed that *repression*, the basic mechanism that banishes anxiety-arousing impulses, enables other defense mechanisms, six of which are listed here.

Defense Mechanism	Unconscious Process Employed to Avoid Anxiety-Arousing Thoughts or Feelings	Example
Regression	Retreating to a more infantile psychosexual stage, where some psychic energy remains fixated.	A little boy reverts to the oral comfort of thumb sucking in the car on the way to his first day of school.
Reaction formation	Switching unacceptable impulses into their opposites.	Repressing angry feelings, a person displays exaggerated friendliness.
Projection	Disguising one’s own threatening impulses by attributing them to others.	“The thief thinks everyone else is a thief” (an El Salvadoran saying).
Rationalization	Offering self-justifying explanations in place of the real, more threatening unconscious reasons for one’s actions.	A habitual drinker says she drinks with her friends “just to be sociable.”
Displacement	Shifting sexual or aggressive impulses toward a more acceptable or less threatening object or person.	A little girl kicks the family dog after her mother sends her to her room.
Denial	Refusing to believe or even perceive painful realities.	A partner denies evidence of his loved one’s affair.

Regression Faced with a mild stressor, children and young orangutans seek protection and comfort from their caregivers. Freud might have interpreted these behaviors as regression, a retreat to an earlier developmental stage.

RETRIEVAL PRACTICE

- According to Freud’s ideas about the three-part personality structure, the _____ operates on the *reality principle* and tries to balance demands in a way that produces long-term pleasure rather than pain; the _____ operates on the *pleasure principle* and seeks immediate gratification; and the _____ represents the voice of our internalized ideals (our *conscience*).
ANSWERS: ego; id; superego
- In the psychoanalytic view, conflicts unresolved during one of the psychosexual stages may lead to _____ at that stage.
ANSWER: fixation
- Freud believed that our defense mechanisms operate _____ (consciously/unconsciously) and defend us against _____.
ANSWERS: unconsciously; anxiety

The Neo-Freudian and Later Psychodynamic Theorists

14-6 Which of Freud’s ideas did his followers accept or reject?

In a historical period when people never talked about sex, and certainly not unconscious desires for sex with one’s parent, Freud’s writings prompted considerable debate. “In the Middle Ages, they would have burned me,” observed Freud to a friend. “Now they are content with burning my books” (Jones, 1957). Despite the controversy, Freud attracted followers. Several young, ambitious physicians formed an inner circle around their strong-minded leader. These pioneering psychoanalysts, whom we often call *neo-Freudians*, adopted Freud’s interviewing technique and accepted Freud’s basic ideas: the personality structures of id, ego, and superego; the importance of the unconscious; the childhood roots of personality; and the dynamics of anxiety and the defense mechanisms. But they broke off from Freud in two important ways. First, they placed more emphasis on the conscious mind’s role in interpreting experience and in coping with the environment. And second, they doubted that sex and aggression were all-consuming motivations. Instead, they tended to emphasize loftier motives and social interactions.

Alfred Adler and Karen Horney [HORN-eye], for example, agreed with Freud that childhood is important. But they believed that childhood *social*, not sexual, tensions are crucial for personality formation (Ferguson, 2003). Adler (who proposed the still popular idea of the *inferiority complex*) had struggled to overcome childhood illnesses and accidents. He believed that much of our behavior is driven by efforts to conquer childhood inferiority feelings that trigger our strivings for superiority and power. Horney said

Alfred Adler “The individual feels at home in life and feels his existence to be worthwhile just so far as he is useful to others and is overcoming feelings of inferiority” (*Problems of Neurosis*, 1964).

Karen Horney “The view that women are infantile and emotional creatures, and as such, incapable of responsibility and independence is the work of the masculine tendency to lower women’s self-respect” (*Feminine Psychology*, 1932).

Carl Jung “From the living fountain of instinct flows everything that is creative; hence the unconscious is the very source of the creative impulse” (*The Structure and Dynamics of the Psyche*, 1960).

childhood anxiety triggers our desire for love and security. She also countered Freud’s assumptions, rooted in his conservative culture, that women have weak superegos and suffer “penis envy,” and she attempted to balance his masculine bias.

Carl Jung started out a strong follower of Freud, but then he veered off on his own. Jung placed less emphasis on social factors and agreed with Freud that the unconscious exerts a powerful influence. But to Jung [Yoong], the unconscious contains more than our repressed thoughts and feelings. He believed we also have a **collective unconscious**, a common reservoir of images, or *archetypes*, derived from our species’ universal experiences. Jung said that the collective unconscious explains why, for many people, spiritual concerns are deeply rooted and why people in different cultures share certain myths and images. Most of today’s psychodynamic psychologists and other psychological theorists discount the idea of inherited experiences, but do believe that our shared evolutionary history shaped some universal dispositions. They are also aware that experience can leave *epigenetic* marks (see Chapter 4).

Freud died in 1939. Since then, some of his ideas have been incorporated into the diversity of perspectives that make up psychodynamic theory. “Most contemporary [psychodynamic] theorists and therapists are not wedded to the idea that sex is the basis of personality,” noted Drew Westen (1996). They “do not talk about ids and egos, and do not go around classifying their patients as oral, anal, or phallic characters.” What they do assume, with Freud and with much support from today’s psychological science, is that much of our mental life is unconscious. With Freud, they also assume that we often struggle with inner conflicts among our wishes, fears, and values, and that childhood shapes our personality and ways of becoming attached to others.

Assessing Unconscious Processes

14-7 What are projective tests, how are they used, and what are some criticisms of them?

Personality tests reflect the basic ideas of particular personality theories. Such tools, useful to those who study personality or provide therapy, are tailored to test specific theories. So, what might be the assessment tool of choice for someone working in the Freudian tradition?

collective unconscious Carl Jung’s concept of a shared, inherited reservoir of memory traces from our species’ history.

©1983 by Sidney Harris, American Scientist Magazine

“The forward thrust of the antlers shows a determined personality, yet the small sun indicates a lack of self-confidence. . . .”

projective test a personality test, such as the Rorschach, that provides ambiguous stimuli designed to trigger projection of one's inner dynamics.

Thematic Apperception Test (TAT) a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes.

Rorschach inkblot test the most widely used projective test, a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people's inner feelings by analyzing their interpretations of the blots.

“We don’t see things as they are; we see things as we are.”

The Talmud

Such a test would need to provide some sort of road into the unconscious, to unearth the residue of early childhood experiences, to move beneath surface pretensions and reveal hidden conflicts and impulses. Objective assessment tools, such as agree-disagree or true-false questionnaires, would be inadequate because they would merely tap the conscious surface.

Projective tests aim to provide this “psychological X-ray,” by asking test-takers to describe an ambiguous stimulus or tell a story about it. The clinician may presume that any hopes, desires, and fears that people see in the ambiguous image are projections of their own inner feelings or conflicts.

Henry Murray (1933) demonstrated a possible basis for such a test at a party hosted by his 11-year-old daughter. Murray engaged the children in a frightening game called “Murder.” When shown some photographs after the game, the children perceived the photos as more malicious than they had before the game. These children, it seemed to Murray, had *projected* their inner feelings into the pictures.

A few years later, Murray introduced the **Thematic Apperception Test (TAT)**—a test in which people view ambiguous pictures and then make up stories about them. One use of such storytelling has been to assess *achievement motivation* (Schultheiss et al., 2014). Shown a daydreaming boy, those who imagine he is fantasizing about an achievement are presumed to be projecting their own goals. “As a rule,” said Murray, “the subject leaves the test happily unaware that he has presented the psychologist with what amounts to an x-ray of his inner self” (quoted by Talbot, 1999).

The most widely used projective test left some blots on the name of Swiss psychiatrist Hermann Rorschach [ROAR-shock; 1884–1922]. He based his famous **Rorschach inkblot test**, in which people describe what they see in a series of inkblots (FIGURE 14.2), on a childhood game. He and his friends would drip ink on a paper, fold it, and then say what they saw in the resulting blot (Sdorow, 2005). Do you see predatory animals or weapons? Perhaps you have aggressive tendencies. But is this a reasonable assumption? The answer varies.

Some clinicians cherish the Rorschach, even offering to judges Rorschach-based assessments of criminals’ violence potential. Others view the test as a source of suggestive leads, an icebreaker, and a revealing interview technique. The Society for Personality Assessment (2005) commends “its responsible use” (which would *not* include inferring past childhood sexual abuse). And—in response to past criticisms of test scoring and interpretation (Sechrest et al., 1998)—a research-based, computer-aided tool has been designed to improve agreement among raters and enhance the test’s validity (Erdberg, 1990; Exner, 2003).

But the evidence is insufficient to its revilers, who insist the Rorschach is no emotional MRI. They argue that only a few of the many Rorschach-derived scores, such as

▼ FIGURE 14.2

The Rorschach test In this projective test, people tell what they see in a series of symmetrical inkblots. Some who use this test are confident that the interpretation of ambiguous stimuli will reveal unconscious aspects of the test-taker’s personality.

Spencer Grant/Science Source

ones for hostility and anxiety, have demonstrated validity (Wood, 2006). Moreover, they say, these tests are not reliable. Inkblot assessments diagnose many normal adults as pathological (Mihura et al., 2013; Wood et al., 2003, 2006, 2010). Alternative projective assessment techniques fare little better. “Even seasoned professionals can be fooled by their intuitions and their faith in tools that lack strong evidence of effectiveness,” warned Scott Lilienfeld, James Wood, and Howard Garb (2001). “When a substantial body of research demonstrates that old intuitions are wrong, it is time to adopt new ways of thinking.”

Evaluating Freud’s Psychoanalytic Perspective and Modern Views of the Unconscious

14-8 How do contemporary psychologists view Freud’s psychoanalysis?

Modern Research Contradicts Many of Freud’s Ideas We critique Freud from a twenty-first-century perspective, a perspective that itself will be subject to revision. Freud did not have access to neurotransmitter or DNA studies, or to all that we have since learned about human development, thinking, and emotion. To criticize his theory by comparing it with today’s thinking, some say, is like criticizing Henry Ford’s Model T by comparing it with today’s hybrid cars. How tempting it always is to judge people in the past from our perspective in the present.

But both Freud’s devotees and detractors agree that recent research contradicts many of his specific ideas. Today’s developmental psychologists see our development as lifelong, not fixed in childhood. They doubt that infants’ neural networks are mature enough to sustain as much emotional trauma as Freud assumed. Some think Freud overestimated parental influence and underestimated peer influence. They also doubt that conscience and gender identity form as the child resolves the Oedipus complex at age 5 or 6. We gain our gender identity earlier, and those who become strongly masculine or feminine do so even without a same-sex parent present. And they note that Freud’s ideas about childhood sexuality arose from his skepticism of stories of childhood sexual abuse told by his female patients—stories that some scholars believe he attributed to their own childhood sexual wishes and conflicts (Esterson, 2001; Powell & Boer, 1994). Today, we understand how Freud’s questioning might have created false memories of abuse, and we also know that childhood sexual abuse does happen.

As we saw in Chapter 3, new ideas about why we dream dispute Freud’s belief that dreams disguise and fulfill wishes. And slips of the tongue can be explained as competition between similar verbal choices in our memory network. Someone who says “I don’t want to do that—it’s a lot of *brothel*” may simply be blending *bother* and *trouble* (Foss & Hakes, 1978). Researchers find little support for Freud’s idea that defense mechanisms disguise sexual and aggressive impulses (though our cognitive gymnastics do indeed work to protect our self-esteem). History also has failed to support another of Freud’s ideas—that suppressed sexuality causes psychological disorders. From Freud’s time to ours, sexual inhibition has diminished; psychological disorders have not.

Psychologists also criticize Freud’s theory for its scientific shortcomings. Recall from Chapter 1 that good scientific theories explain observations and offer testable hypotheses. Freud’s theory rests on few objective observations, and parts of it offer few testable hypotheses. For Freud, his own recollections and interpretations of patients’ free associations, dreams, and slips were evidence enough.

What is the most serious problem with Freud’s theory? It offers after-the-fact explanations of any characteristic (of one person’s smoking, another’s fear of horses, another’s sexual orientation) yet fails to *predict* such behaviors and traits. If

“The Rorschach [Inkblot Test] has the dubious distinction of being, simultaneously, the most cherished and the most reviled of all psychological assessment tools.”

John Hunsley and J. Michael Bailey, 1999

“Many aspects of Freudian theory are indeed out of date, and they should be: Freud died in 1939, and he has been slow to undertake further revisions.”

Psychologist Drew Westen (1998)

“We are arguing like a man who should say, ‘If there were an invisible cat in that chair, the chair would look empty; but the chair does look empty; therefore there is an invisible cat in it.’”

C. S. Lewis, *Four Loves*, 1958

“Although [Freud] clearly made a number of mistakes in the formulation of his ideas, his understanding of unconscious mental processes was pretty much on target. In fact, it is very consistent with modern neuroscientists’ belief that most mental processes are unconscious.”

Nobel Prize-winning neuroscientist
Eric Kandel (2012)

“The overall findings . . . seriously challenge the classical psychoanalytic notion of repression.”

Psychologist Yacov Rofé,
“Does Repression Exist?” 2008

“During the Holocaust, many children . . . were forced to endure the unendurable. For those who continue to suffer [the] pain is still present, many years later, as real as it was on the day it occurred.”

Eric Zillmer, Molly Harrower,
Barry Ritzler, and Robert Archer,
The Quest for the Nazi Personality, 1995

you feel angry at your mother’s death, you illustrate his theory because “your unresolved childhood dependency needs are threatened.” If you do not feel angry, you again illustrate his theory because “you are repressing your anger.” That “is like betting on a horse after the race has been run” (Hall & Lindzey, 1978, p. 68). A good theory makes testable predictions.

So, should psychology post an “Allow Natural Death” order on this old theory? Freud’s supporters object. To criticize Freudian theory for not making testable predictions is, they say, like criticizing baseball for not being an aerobic exercise, something it was never intended to be. Freud never claimed that psychoanalysis was predictive science. He merely claimed that, looking back, psychoanalysts could find meaning in our state of mind (Rieff, 1979).

Freud’s supporters also note that some of his ideas *are* enduring. It was Freud who drew our attention to the unconscious and the irrational, at a time when such ideas were not popular. Today many researchers study our irrationality (Ariely, 2010). Psychologist Daniel Kahneman won the 2002 Nobel Prize in Economics for his studies of our faulty decision making. Freud also drew our attention to the importance of human sexuality, and to the tension between our biological impulses and our social well-being. It was Freud who challenged our self-righteousness, exposed our self-protective defenses, and reminded us of our potential for evil.

Modern Research Challenges the Idea of Repression Psychoanalytic theory presumes that we often *repress* offending wishes, banishing them into the unconscious until they resurface, like long-lost books in a dusty attic. Recover and resolve childhood’s conflicted wishes, and emotional healing should follow. Repression became a widely accepted concept, used to explain hypnotic phenomena and psychological disorders. Some psychodynamic followers extended repression to explain apparently lost and recovered memories of childhood traumas (Boag, 2006; Cheit, 1998; Erdelyi, 2006). In one survey, 88 percent of university students believed that painful experiences commonly get pushed out of awareness and into the unconscious (Garry et al., 1994).

Today’s researchers agree that we sometimes spare our egos by neglecting threatening information (Green et al., 2008). Yet many contend that repression, if it ever occurs, is a rare mental response to terrible trauma. Even those who witnessed a parent’s murder or survived Nazi death camps have retained their unrepressed memories of the horror (Helmreich, 1992, 1994; Malmquist, 1986; Pennebaker, 1990). “Dozens of formal studies have yielded not a single convincing case of repression in the entire literature on trauma,” concluded personality researcher John Kihlstrom (2006).

Some researchers do believe that extreme, prolonged stress, such as the stress some severely abused children experience, might disrupt memory by damaging the hippocampus (Schacter, 1996). But the far more common reality is that high stress and associated stress hormones *enhance* memory. Indeed, rape, torture, and other traumatic events haunt survivors, who experience unwanted flashbacks. They are seared onto the soul. “You see the babies,” said Holocaust survivor Sally H. (1979). “You see the screaming mothers. You see hanging people. You sit and you see that face there. It’s something you don’t forget.”

The Modern Unconscious Mind

14-9 How has modern research developed our understanding of the unconscious?

Freud was right about a big idea that underlies today’s psychodynamic thinking: We indeed have limited access to all that goes on in our minds (Erdelyi, 1985, 1988, 2006; Norman, 2010). Our two-track mind has a vast out-of-sight realm. Some researchers even argue that “most of a person’s everyday life is determined by unconscious thought processes” (Bargh & Chartrand, 1999).

Nevertheless, many research psychologists now think of the unconscious not as seething passions and repressive censoring but as cooler information processing that occurs without our awareness. To these researchers, the unconscious also involves

- the schemas that automatically control our perceptions and interpretations (Chapter 6).
- the priming by stimuli to which we have not consciously attended (Chapters 6 and 8).
- the right-hemisphere activity that enables the split-brain patient's left hand to carry out an instruction the patient cannot verbalize (Chapter 2).
- the implicit memories that operate without conscious recall, even among those with amnesia (Chapter 8).
- the emotions that activate instantly, before conscious analysis (Chapter 12).
- the stereotypes that automatically and unconsciously influence how we process information about others (Chapter 13).

More than we realize, we fly on autopilot. Our mind wanders, activating the brain's "default network" (Mason et al., 2007). Unconscious processing occurs constantly. Like an enormous ocean, the unconscious mind is huge. This understanding of unconscious information processing is more like the pre-Freudian view of an underground, untended stream of thought from which spontaneous behavior and creative ideas surface (Bargh & Morsella, 2008).

There is also research support for two of Freud's defense mechanisms. For example, one study demonstrated *reaction formation* (trading unacceptable impulses for their opposite). Men who reported strong anti-gay attitudes, compared with those who did not report such attitudes, experienced greater physiological arousal when watching videos of homosexual men having sex (as measured with an instrument that measures bloodflow to the penis) even though they said the films did not make them sexually aroused (Adams et al., 1996). Likewise, preliminary evidence suggests that people who unconsciously identify as homosexual—but who consciously identify as straight—report more negative attitudes toward gays and less support for pro-gay policies (Weinstein et al., 2012).

Freud's *projection* (attributing our own threatening impulses to others) has also been confirmed. People do tend to see their traits, attitudes, and goals in others (Baumeister et al., 1998; Maner et al., 2005). Today's researchers call this the *false consensus effect*—the tendency to overestimate the extent to which others share our beliefs and behaviors. People who binge-drink or break speed limits tend to think many others do the same. However, defense mechanisms don't work exactly as Freud supposed. They seem motivated less by the sexual and aggressive undercurrents he imagined than by our need to protect our self-image.

Finally, research has supported Freud's idea that we unconsciously defend ourselves against anxiety. Researchers have proposed that one source of anxiety is "the terror resulting from our awareness of vulnerability and death" (Greenberg et al., 1997). Nearly 300 experiments testing **terror-management theory** show that thinking about one's mortality—for example, by writing a short essay on dying and its associated emotions—provokes various terror-management defenses (Burke et al., 2010). For example, death anxiety increases aggression toward rivals and esteem for oneself (Cohen & Solomon, 2011; Koole et al., 2006).

Faced with a threatening world, people act not only to enhance their self-esteem but also to adhere more strongly to worldviews that answer questions about life's meaning. The prospect of death promotes religious sentiments, and deep religious convictions enable people to be less defensive—less likely to rise in defense of their worldview—when reminded of death (Jonas & Fischer, 2006; Norenzayan & Hansen, 2006). Moreover, when contemplating death, people prioritize their close relationships (Cox

terror-management theory a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death.

"It says, 'Someday you will die.'"

"I sought the Lord, and he answered me and delivered me out of all my terror."

Psalms 34:4

& Arndt, 2012; Mikulincer et al., 2003). The actual death of loved ones can provoke protective responses as well. For years, I [ND] have studied the way people respond to thoughts about death (Kashdan et al., 2014). It has been fascinating, but not enough to get me off the couch. The shock of my own mother’s unexpected death, however, motivated me to start running again, and to live a healthier lifestyle (Hayasaki, 2014). Facing death can inspire us to affirm life.

RETRIEVAL PRACTICE

- What are three big ideas that have survived from Freud’s work in psychoanalytic theory? What are three ways in which Freud’s work has been criticized?

ANSWER: Freud first drew attention to (1) the importance of childhood experiences, (2) the existence of the unconscious mind, and (3) our self-protective defense mechanisms. Freud’s work has been criticized as (1) not scientifically testable and offering after-the-fact explanations, (2) focusing too much on sexual conflicts in childhood, and (3) based on the idea of repression, which has not been supported by modern research.

- Which elements of traditional psychoanalysis have modern-day *psychodynamic* theorists and therapists retained, and which elements have they mostly left behind?

ANSWER: Today’s psychodynamic theorists and therapists still rely on the interviewing techniques that Freud used, and they still tend to focus on childhood experiences and attachments, unresolved conflicts, and unconscious influences. However, they are not likely to dwell on fixation at any psychosexual stage, or the idea that resolution of sexual issues is the basis of our personality.

REVIEW Introduction to Personality and Psychodynamic Theories

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

Humanistic Theories and Trait Theories

Humanistic Theories

14-10 How did humanistic psychologists view personality, and what was their goal in studying personality?

BY THE 1960s, SOME PERSONALITY psychologists had become discontented with the sometimes bleak focus on drives and conflicts in psychodynamic theory and the mechanistic psychology of B. F. Skinner's *behaviorism* (see Chapter 7). In contrast to Sigmund Freud's emphasis on disorders born out of dark conflicts, these **humanistic theorists** focused on the ways people strive for self-determination and self-realization. In contrast to behaviorism's scientific objectivity, they studied people through their own self-reported experiences and feelings.

Two pioneering theorists—Abraham Maslow (1908–1970) and Carl Rogers (1902–1987)—offered a *third-force perspective* that emphasized human potential.

Abraham Maslow's Self-Actualizing Person

Maslow proposed that we are motivated by a *hierarchy of needs* (Chapter 11). If our physiological needs are met, we become concerned with personal safety; if we achieve a sense of security, we then seek to love, to be loved, and to love ourselves; with our love needs satisfied, we seek self-esteem. Having achieved self-esteem, we ultimately seek **self-actualization** (the process of fulfilling our potential) and *self-transcendence* (meaning, purpose, and communion beyond the self).

Maslow (1970) developed his ideas by studying healthy, creative people rather than troubled clinical cases. He based his description of self-actualization on a study of those, such as Abraham Lincoln, who seemed notable for their rich and productive lives. Maslow reported that such people shared certain characteristics: They were self-aware and self-accepting, open and spontaneous, loving and caring, and not paralyzed by others' opinions. Secure in their sense of who they were, their interests were problem-centered rather than self-centered. They focused their energies on a particular task, one they often regarded as their mission in life. Most enjoyed a few deep relationships rather than many superficial ones. Many had been moved by spiritual or personal *peak experiences* that surpassed ordinary consciousness.

These, said Maslow, are mature adult qualities found in those who have learned enough about life to be compassionate, to have outgrown their mixed feelings toward their parents, to have found their calling, to have “acquired enough courage to be unpopular, to be unashamed about being openly virtuous.” Maslow's work with college students led him to speculate that those likely to become self-actualizing adults were likable, caring, “privately affectionate to those of their elders who deserve it,” and “secretly uneasy about the cruelty, meanness, and mob spirit so often found in young people.”

Carl Rogers' Person-Centered Perspective

Fellow humanistic psychologist Carl Rogers agreed with much of Maslow's thinking. Rogers' *person-centered perspective* held that people are basically good and are endowed with self-actualizing tendencies. Unless thwarted by an environment that inhibits growth, each of us is like an acorn, primed for growth and fulfillment. Rogers (1980) believed that a growth-promoting climate required three conditions.

Abraham Maslow “Any theory of motivation that is worthy of attention must deal with the highest capacities of the healthy and strong person as well as with the defensive maneuvers of crippled spirits” (*Motivation and Personality*, 1970, p. 33).

humanistic theories view personality with a focus on the potential for healthy personal growth.

self-actualization according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential.

A father *not* offering unconditional positive regard:

“Just remember, son, it doesn’t matter whether you win or lose—unless you want Daddy’s love.”

The picture of empathy Being open and sharing confidences is easier when the listener shows real understanding. Within such relationships we can relax and fully express our true selves. Consider a conversation when you knew someone was waiting for their turn to speak instead of listening to you. Now consider the last time someone heard you with empathy. How did those two experiences differ?

unconditional positive regard according to Rogers, an attitude of total acceptance toward another person.

self-concept all our thoughts and feelings about ourselves, in answer to the question, “Who am I?”

- **Genuineness:** When people are *genuine*, they are open with their own feelings, drop their facades, and are transparent and self-disclosing.
- **Acceptance:** When people are *accepting*, they offer **unconditional positive regard**, an attitude of grace that values us even knowing our failings. It is a profound relief to drop our pretenses, confess our worst feelings, and discover that we are still accepted. In a good marriage, a close family, or an intimate friendship, we are free to be spontaneous without fearing the loss of others’ esteem.
- **Empathy:** When people are *empathic*, they share and mirror other’s feelings and reflect their meanings. “Rarely do we listen with real understanding, true empathy,” said Rogers. “Yet listening, of this very special kind, is one of the most potent forces for change that I know.”

Genuineness, acceptance, and empathy are, Rogers believed, the water, sun, and nutrients that enable people to grow like vigorous oak trees. For “as persons are accepted and prized, they tend to develop a more caring attitude toward themselves” (Rogers, 1980, p. 116). As persons are empathically heard, “it becomes possible for them to listen more accurately to the flow of inner experiencings.”

Writer Calvin Trillin (2006) recalled an example of parental genuineness and acceptance at a camp for children with severe disorders, where his wife, Alice, worked. L., a “magical child,” had genetic diseases that meant she had to be tube-fed and could walk only with difficulty. Alice recalled,

One day, when we were playing duck-duck-goose, I was sitting behind her and she asked me to hold her mail for her while she took her turn to be chased around the circle. It took her a while to make the circuit, and I had time to see that on top of the pile [of mail] was a note from her mom. Then I did something truly awful. . . . I simply had to know what this child’s parents could have done to make her so spectacular, to make her the most optimistic, most enthusiastic, most hopeful human being I had ever encountered. I snuck a quick look at the note, and my eyes fell on this sentence: “If God had given us all of the children in the world to choose from, L., we would only have chosen you.” Before L. got back to her place in the circle, I showed the note to Bud, who was sitting next to me. “Quick. Read this,” I whispered. “It’s the secret of life.”

Maslow and Rogers would have smiled knowingly. For them, a central feature of personality is one’s **self-concept**—all the thoughts and feelings we have in response to the question, “Who am I?” If our self-concept is positive, we tend to act and perceive the world positively. If it is negative—if in our own eyes we fall far short of our *ideal self*—said Rogers, we feel dissatisfied and unhappy. A worthwhile goal for therapists, parents, teachers, and friends is therefore, he said, to help others know, accept, and be true to themselves.

Assessing the Self

14-11 How did humanistic psychologists assess a person’s sense of self?

Humanistic psychologists sometimes assessed personality by asking people to fill out questionnaires that would evaluate their self-concept. One questionnaire, inspired by Carl Rogers, asked people to describe themselves both as they would *ideally* like to be and as they *actually* are. When the ideal and the actual self are nearly alike, said Rogers, the self-concept is positive. Assessing his clients’ personal growth during therapy, he looked for successively closer ratings of actual and ideal selves.

Some humanistic psychologists believed that any standardized assessment of personality, even a questionnaire, is depersonalizing. Rather than forcing the person to respond to narrow categories, these humanistic psychologists presumed that interviews and intimate conversation would provide a better understanding of each person’s unique experiences.

Evaluating Humanistic Theories

14-12 How have humanistic theories influenced psychology? What criticisms have they faced?

One thing said of Freud can also be said of the humanistic psychologists: Their impact has been pervasive. Maslow's and Rogers' ideas have influenced counseling, education, child raising, and management. And they laid the groundwork for today's scientific positive psychology (Chapter 12).

They have also influenced—sometimes in unintended ways—much of today's popular psychology. Is a positive self-concept the key to happiness and success? Do acceptance and empathy nurture positive feelings about oneself? Are people basically good and capable of self-improvement? Many people answer *Yes, Yes, and Yes*. In 2006, U.S. high school students reported notably higher self-esteem and greater expectations of future career success than did students living in 1975 (Twenge & Campbell, 2008). Given a choice, today's North American collegians mostly say they'd rather get a self-esteem boost, such as a compliment or good grade on a paper, than enjoy a favorite food or sexual activity (Bushman et al., 2011). Humanistic psychology's message has been heard.

The prominence of the humanistic perspective set off a backlash of criticism. First, said the critics, its concepts are vague and *subjective*. Consider Maslow's description of self-actualizing people as open, spontaneous, loving, self-accepting, and productive. Is this a scientific description? Or is it merely a description of the theorist's own values and ideals? Maslow, noted M. Brewster Smith (1978), offered impressions of his own personal heroes. Imagine another theorist who began with a different set of heroes—perhaps Napoleon, John D. Rockefeller, Sr., and Donald Trump. This theorist would likely describe self-actualizing people as “undeterred by others' needs and opinions,” “motivated to achieve,” and “comfortable with power.”

Critics also objected to the idea that, as Rogers put it, “The only question which matters is, ‘Am I living in a way which is deeply satisfying to me, and which truly expresses me?’” (quoted by Wallach & Wallach, 1985). This emphasis on *individualism*—trusting and acting on one's feelings, being true to oneself, fulfilling oneself—could lead to self-indulgence, selfishness, and an erosion of moral restraint (Campbell & Specht, 1985; Wallach & Wallach, 1983). Imagine working on a group project with people who refuse to complete any task that is not deeply satisfying or does not truly express their identity.

Humanistic psychologists reply that a secure, nondefensive self-acceptance is actually the first step toward loving others. Indeed, people who feel intrinsically liked and accepted—for who they are, not just for their achievements—exhibit less defensive attitudes (Schimel et al., 2001). Those feeling liked and accepted by a romantic partner report being happier in their relationships and acting more kindly toward their partner (Gordon & Chen, 2010).

A final accusation leveled against humanistic psychology is that it is *naïve*, that it fails to appreciate the reality of our human capacity for evil. Faced with climate change, overpopulation, terrorism, and the spread of nuclear weapons, we may become apathetic from either of two rationalizations. One is a starry-eyed optimism that denies the threat (“People are basically good; everything will work out”). The other is a dark despair (“It's hopeless; why try?”). Action requires enough realism to fuel concern and enough optimism to provide hope. Humanistic psychology, say the critics, encourages the needed hope but not the equally necessary realism about evil.

“We do pretty well when you stop to think that people are basically good.”

RETRIEVAL PRACTICE

- How did *humanistic psychology* provide a fresh perspective?
ANSWER: This movement sought to turn psychology's attention away from drives and conflicts and toward our growth potential, with a focus on the way healthy people strive for self-determination and self-actualization, which was in contrast to Freudian theory and strict behaviorism.
- What does it mean to be *empathic*? How about *self-actualized*? Which humanistic psychologists used these terms?
ANSWERS: To be *empathic* is to share and mirror another person's feelings. Carl Rogers believed that people nurture growth in others by being empathic. Abraham Maslow proposed that *self-actualization* is the motivation to fulfill one's potential, and one of the ultimate psychological needs (the other is self-transcendence).

Trait Theories

14-13 How do psychologists use traits to describe personality?

Rather than focusing on unconscious forces and thwarted growth opportunities, some researchers attempt to define personality in terms of stable and enduring behavior patterns, such as Lady Gaga's openness to new experiences and her self-discipline. This perspective can be traced in part to a remarkable meeting in 1919, when Gordon Allport, a curious 22-year-old psychology student, interviewed Sigmund Freud in Vienna. Allport soon discovered just how preoccupied the founder of psychoanalysis was with finding hidden motives, even in Allport's own behavior during the interview. That experience ultimately led Allport to do what Freud did not do—to describe personality in terms of fundamental **traits**—people's characteristic behaviors and conscious motives (such as the curiosity that actually motivated Allport to see Freud). Meeting Freud, said Allport, “taught me that [psychoanalysis], for all its merits, may plunge too deep, and that psychologists would do well to give full recognition to manifest motives before probing the unconscious.” Allport came to define personality in terms of identifiable behavior patterns. He was concerned less with *explaining* individual traits than with *describing* them.

Like Allport, Isabel Briggs Myers (1987) and her mother, Katharine Briggs, wanted to describe important personality differences. They attempted to sort people according to Carl Jung's personality types, based on their responses to 126 questions. The *Myers-Briggs Type Indicator (MBTI)*, available in 30 languages, has been taken by more than 2 million people a year, mostly for counseling, leadership training, and work-team development (CPP, 2008). It offers choices, such as “Do you usually value sentiment more than logic, or value logic more than sentiment?” Then it counts the test-taker's preferences, labels them as indicating, say, a “feeling type” or “thinking type,” and feeds them back to the person in complimentary terms. Feeling types, for example, are told they are “sympathetic, appreciative, and tactful”; thinking types are told they are “good at analyzing.” (Every type has its strengths, so everyone is affirmed.)

Most people agree with their announced type profile, which mirrors their declared preferences. They may also accept their label as a basis for being matched with work partners and tasks that supposedly suit their temperaments. But growing research suggests that people should not blindly accept the validity of their test results. A National Research Council report noted that despite the test's popularity in business and career counseling, its initial use outran research on its value as a predictor of job performance, and “the popularity of this instrument in the absence of proven scientific worth is troublesome” (Druckman & Bjork, 1991, p. 101; see also Pittenger, 1993). Although research on the MBTI has been accumulating since those cautionary words were expressed, the test remains mostly a counseling and coaching tool, not a research instrument.

trait a characteristic pattern of behavior or a disposition to feel and act, as assessed by self-report inventories and peer reports.

Exploring Traits

Classifying people as one or another distinct personality type fails to capture their full individuality. We are each a unique complex of multiple traits. So how else could we describe our personalities? We might describe an apple by placing it along several trait dimensions—relatively large or small, red or green, sweet or sour. By placing people on several trait dimensions simultaneously, psychologists can describe countless individual personality variations. (Remember from Chapter 6 that variations on just three color dimensions—hue, saturation, and brightness—create many thousands of colors.)

What trait dimensions describe personality? If you had an upcoming blind date, what personality traits might give you an accurate sense of the person? Allport and his associate H. S. Odbert (1936) counted all the words in an unabridged dictionary with which one could describe people. There were almost 18,000! How, then, could psychologists condense the list to a manageable number of basic traits?

Factor Analysis One technique is *factor analysis*, a statistical procedure that has also been used to identify clusters (factors) of test items that tap basic components of intelligence (such as spatial ability or verbal skill). Imagine that people who describe themselves as outgoing also tend to say that they like excitement and practical jokes and dislike quiet reading. Such a statistically correlated cluster of behaviors reflects a basic factor, or trait—in this case, *extraversion*.

British psychologists Hans Eysenck and Sybil Eysenck [EYE-zink] believed that we can reduce many of our normal individual variations to two or three dimensions, including *extraversion–introversion* and *emotional stability–instability* (FIGURE 14.3). People in 35 countries around the world, from China to Uganda to Russia, have taken the *Eysenck Personality Questionnaire*. When their answers were analyzed, the extraversion and emotionality factors inevitably emerged as basic personality dimensions (Eysenck, 1990, 1992). The Eysencks believed, and research confirms, that these factors are genetically influenced.

Biology and Personality Brain-activity scans of extraverts add to the growing list of traits and mental states now being explored with brain-imaging procedures. Such studies indicate that extraverts seek stimulation because their normal *brain arousal* is relatively low. For example, PET scans show that a frontal lobe area involved in behavior inhibition is less active in extraverts than in introverts (Johnson et al., 1999). Dopamine and dopamine-related neural activity tend to be higher in extraverts (Kim et al., 2008; Wacker et al., 2006).

“Russ is the sort of person who never wants to be alone with his thoughts.”

▼ FIGURE 14.3

Two personality dimensions

Mapmakers can tell us a lot by using two axes (north–south and east–west). Two primary personality factors (extraversion–introversion and stability–instability) are similarly useful as axes for describing personality variation. Varying combinations define other, more specific traits. (from Eysenck & Eysenck, 1963). Those who are naturally introverted, such as primatologist Jane Goodall, may be particularly gifted in field studies. Successful politicians, including former U.S. President Bill Clinton, are often natural extraverts.

Our biology influences our personality in other ways as well. As you may recall from the twin and adoption studies in Chapter 4, our genes have much to say about the temperament and behavioral style that help define our personality. Jerome Kagan, for example, has attributed differences in children's shyness and inhibition to their autonomic nervous system reactivity (see *Thinking Critically About: The Stigma of Introversion*). Those with a reactive autonomic nervous system respond to stress with greater anxiety and inhibition. The fearless, curious child may become the rock-climbing or fast-driving adult.

Personality differences among dogs (in energy, affection, reactivity, and curious intelligence) are as evident, and as consistently judged, as personality differences among humans (Gosling et al., 2003; Jones & Gosling, 2005).

THINKING CRITICALLY ABOUT

The Stigma of Introversion

14-14 What are some common misunderstandings about introversion? Does extraversion lead to greater success than introversion?

Psychologists describe personality, but they don't advise which traits people should have. Society does this. Western cultures, for example, prize extraversion. Being introverted may imply that you don't have the "right stuff" (Cain, 2012).

Just look at our superheroes. Extraverted Superman is bold and energetic. His introverted alter ego, Clark Kent, is mild-mannered and bumbling. The message is clear: If you're a superhero, you're an extravert.

TV shows also portray heartthrobs and examples of success as extraverts. Don Draper, the highly successful, attractive advertising executive in the show *Mad Men* is a classic extravert. He is dominant and charismatic. Women clamor for his attention. Again, the point is plain: Extraversion equals success.

Why do we so often celebrate extraversion and belittle introversion? Many people may not understand what introversion really is. People tend to equate introversion with shyness, but the two concepts differ. Introverted people seek low levels of stimulation from their environment because they're sensitive. One classic study suggested that introverted people even have greater taste sensitivity. When given lemon juice, introverted people salivated more than extraverted people (Corcoran, 1964). Shy people, in contrast, remain quiet because they fear others will evaluate them negatively.

People may also believe that introversion acts as a barrier to success. On the contrary, introversion has its benefits; as supervisors, introverts show greater receptiveness when their employees voice their ideas, challenge existing norms, and take charge.

AMC/The Kobal Collection/Art Resource

Under these circumstances, introverted leaders outperform extraverted ones (Grant et al., 2011). In fact, one striking analysis of 35 studies showed no correlation between extraversion and sales performance (Barrick et al., 2001). Perhaps the best example of the misperception that introversion hinders career success lies in the American presidency: The American president who is most consistently ranked number one of all time was introverted. His name was Abraham Lincoln.

So, introversion should not be a sign of weakness. Those who need a quiet break from a loud party are not social rejects or incapable of great things. They simply know how to pick an environment where they can thrive. It's important for extraverts to understand that not everyone needs high levels of stimulation. It's not a crime to unwind.

John Parrot/Stocktrek Images/Getty Images

Monkeys, chimpanzees, orangutans, and even birds also have stable personalities (Weiss et al., 2006). Among the Great Tit (a European relative of the American chickadee), bold birds more quickly inspect new objects and explore trees (Groot-huis & Carere, 2005; Verbeek et al., 1994). By selective breeding, researchers can produce bold or shy birds. Both have their place in natural history: In lean years, bold birds are more likely to find food; in abundant years, shy birds feed with less risk.

RETRIEVAL PRACTICE

- Which two primary dimensions did Hans Eysenck and Sybil Eysenck propose for describing personality variation?

ANSWER: introversion–extraversion and emotional stability–instability

Assessing Traits

14-15 What are personality inventories, and what are their strengths and weaknesses as trait-assessment tools?

If stable and enduring traits guide our actions, can we devise valid and reliable tests of them? Several trait assessment techniques exist—some more valid than others. Some provide quick assessments of a single trait, such as extraversion, anxiety, or self-esteem. **Personality inventories**—longer questionnaires covering a wide range of feelings and behaviors—assess several traits at once.

The classic personality inventory is the **Minnesota Multiphasic Personality Inventory (MMPI)**. Although the MMPI was originally developed to identify emotional disorders, it also assesses people's personality traits. One of its creators, Starke Hathaway (1960), compared his effort to that of Alfred Binet. Binet, as you may recall from Chapter 10, developed the first intelligence test by selecting items that identified children who would probably have trouble progressing normally in French schools. Like Binet's items, the MMPI items were **empirically derived**. From a large pool of items, Hathaway and his colleagues selected those on which particular diagnostic groups differed. They then grouped the questions into 10 clinical scales, including scales that assess depressive tendencies, masculinity–femininity, and introversion–extraversion.

Hathaway and others initially gave hundreds of true-false statements (“No one seems to understand me”; “I get all the sympathy I should”; “I like poetry”) to groups of psychologically disordered patients and to “normal” people. They retained any statement—no matter how silly it sounded—on which the patient group's answer differed from that of the normal group. “Nothing in the newspaper interests me except the comics” may seem senseless, but it just so happened that depressed people were more likely to answer *True*. Today's MMPI-2 also has scales assessing, for instance, work attitudes, family problems, and anger.

In contrast to the subjectivity of most projective tests, personality inventories are scored objectively. (Software can administer and score these tests, and can also provide descriptions of people who previously responded similarly.) Objectivity does not, however, guarantee validity. For example, individuals taking the MMPI for employment purposes can give socially desirable answers to create a good impression. But in so doing they may also score high on a *lie scale* that assesses faking (as when people respond *False* to a universally true statement such as “I get angry sometimes”). The objectivity of the MMPI has contributed to its popularity and to its translation into more than 100 languages.

personality inventory a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits.

Minnesota Multiphasic Personality Inventory (MMPI) the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes.

empirically derived test a test (such as the MMPI) developed by testing a pool of items and then selecting those that discriminate between groups.

HOW WOULD YOU KNOW?

Might astrology hold the secret to our personality traits? To consider this question, visit LaunchPad's *How Would You Know If Astrologers Can Describe People's Personality?*

People have had fun spoofing the MMPI with their own mock items: “Weeping brings tears to my eyes,” “Frantic screams make me nervous,” and “I stay in the bathtub until I look like a raisin” (Frankel et al., 1983).

The Big Five Factors

14-16 Which traits seem to provide the most useful information about personality variation?

Today’s trait researchers believe that simple trait factors, such as the Eysencks’ introversion–extraversion and stability–instability dimensions, are important, but they do not tell the whole story. A slightly expanded set of factors—dubbed the *Big Five*—does a better job (Costa & McCrae, 2011). If a test specifies where you are on the five dimensions (conscientiousness, agreeableness, neuroticism, openness, and extraversion; see TABLE 14.3), it has said much of what there is to say about your personality. Around the world—across 56 nations and 29 languages in one study (Schmitt et al., 2007)—people describe others in terms roughly consistent with this list. The Big Five may not be the last word. Some researchers report it takes only one or two or three factors—such as conscientiousness, agreeableness, and extraversion—to describe the basic personality dimensions (Block, 2010; De Raad et al., 2010; Rushton & Irwing, 2011). But for now, at least, five is the winning number in the personality lottery (Heine & Buchtel, 2009; McCrae, 2009). The Big Five—today’s “common currency for personality psychology” (Funder, 2001)—has been the most active personality research topic since the early 1990s and is currently our best approximation of the basic trait dimensions.

Big Five research has explored various questions:

- **How stable are these traits?** One research team analyzed 1.25 million participants ages 10 to 65. They learned that personality continues to develop and change through late childhood and adolescence. By adulthood, our traits have become fairly stable, though conscientiousness, agreeableness, openness, and extraversion continue to increase into middle age, and neuroticism (emotional instability) decreases (Soto et al., 2011).
- **How heritable are they?** Heritability (the extent to which individual differences are attributable to genes) varies with the diversity of people studied, but it generally runs 50 percent or a tad more for each dimension, and genetic influences are similar in different nations (Loehlin et al., 1998; Yamagata et al., 2006). Many genes, each having small effects, combine to influence our traits (McCrae et al., 2010).

▼ TABLE 14.3
The “Big Five” Personality Factors

Researchers use self-report inventories and peer reports to assess and score the Big Five personality factors.

(Memory tip: Picturing a CANOE will help you recall these.)		
Disorganized, careless, impulsive	Conscientiousness	Organized, careful, disciplined
Ruthless, suspicious, uncooperative	Agreeableness	Soft-hearted, trusting, helpful
Calm, secure, self-satisfied	Neuroticism (emotional stability vs. instability)	Anxious, insecure, self-pitying
Practical, prefers routine, conforming	Openness	Imaginative, prefers variety, independent
Retiring, sober, reserved	Extraversion	Sociable, fun-loving, affectionate

Source: Adapted from McCrae & Costa (1986, 2008).

Steve Wisbauer/Getty Images

- **Do these traits reflect differing brain structure?** The size of different brain regions correlates with several Big Five traits (DeYoung et al., 2010). For example, those who score high on conscientiousness tend to have a larger frontal lobe area that aids in planning and controlling behavior. Brain connections also influence the Big Five traits (Adelstein et al., 2011). People high in openness have brains that are wired to experience intense imagination, curiosity, and fantasy.
- **Have these traits changed over time?** Cultures change over time, which can influence shifts in personality. Within the United States and the Netherlands, extraversion and conscientiousness have increased (Mroczek & Spiro, 2003; Smits et al., 2011; Twenge, 2001).
- **How well do these traits apply to various cultures?** The Big Five dimensions describe personality in various cultures reasonably well (Schmitt et al., 2007; Yamagata et al., 2006). “Features of personality traits are common to all human groups,” concluded Robert McCrae and 79 co-researchers (2005) from their 50-culture study.
- **Do the Big Five traits predict our actual behaviors?** Yes. If people report being outgoing, conscientious, and agreeable, “they probably are telling the truth,” reports Big Five researcher Robert McCrae (2011). For example, introverts more than extraverts prefer communicating by e-mail rather than face-to-face (Hertel et al., 2008). Our traits also appear in our language patterns. In text messaging, extraversion predicts use of personal pronouns. Agreeableness predicts positive-emotion words. Neuroticism (emotional instability) predicts negative-emotion words (Holtgraves, 2011).

By exploring such questions, Big Five research has sustained trait psychology and renewed appreciation for the importance of personality. Traits matter.

RETRIEVAL PRACTICE

- What are the *Big Five* personality factors, and why are they scientifically useful?

ANSWER: The Big Five personality factors are conscientiousness, agreeableness, neuroticism (emotional instability vs. instability), openness, and extraversion (CANOE). These factors may be objectively measured, and research suggests that these factors are relatively stable over the life span and apply to all cultures in which they have been studied.

Evaluating Trait Theories

14-17 Does research support the consistency of personality traits over time and across situations?

Are our personality traits stable and enduring? Or does our behavior depend on where and with whom we find ourselves? In some ways, our personality seems stable. Cheerful, friendly children tend to become cheerful, friendly adults. At a recent college reunion, I [DM] was amazed to find that my jovial former classmates were still jovial, the shy ones still shy, the happy-seeming people still smiling and laughing—50 years later. But it’s also true that a fun-loving jokester can suddenly turn serious and respectful at a job interview. The personality traits we express can change from one situation to another.

The Person-Situation Controversy Our behavior is influenced by the interaction of our inner disposition with our environment. Still, the question lingers: Which is more important? When we explore this *person-situation controversy*, we look for genuine personality traits that persist over time *and* across situations. Are some people

“There is as much difference between us and ourselves, as between us and others.”

Michel de Montaigne, *Essays*, 1588

Roughly speaking, the temporary, external influences on behavior are the focus of social psychology, and the enduring, inner influences are the focus of personality psychology. In actuality, behavior always depends on the interaction of persons with situations.

Change and consistency can co-exist. If all people were to become somewhat less shy with age, there would be personality change, but also relative stability and predictability.

▼ **FIGURE 14.4**
Personality stability With age, personality traits become more stable, as reflected in the stronger correlation of trait scores with follow-up scores seven years later. (Data from Roberts & DelVecchio, 2000.)

dependably conscientious and others unreliable, some cheerful and others dour, some friendly and outgoing and others shy? If we are to consider friendliness a trait, friendly people must act friendly at different times and places. Do they?

In earlier chapters, we considered research that has followed lives through time. We noted that some scholars (especially those who study infants) are impressed with personality change; others are struck by personality stability during adulthood. As **FIGURE 14.4** illustrates, data from 152 long-term studies reveal that personality trait scores are positively correlated with scores obtained seven years later, and that as people grow older their personality stabilizes. Interests may change—the avid tropical-fish collector may become an avid gardener. Careers may change—the determined salesperson may become a determined social worker. Relationships may change—the hostile spouse may start over with a new partner. But most people recognize their traits as their own, as Robert McCrae and Paul Costa noted (1994), “and it is well that they do. A person’s recognition of the inevitability of his or her one and only personality is . . . the culminating wisdom of a lifetime.”

So most people—including most psychologists—would probably presume the stability of personality traits. Moreover, our traits are socially significant. They influence our health, our thinking, and our job choices and performance (Deary & Matthews, 1993; Hogan, 1998; Jackson et al., 2012; Sutin et al., 2011). Studies that follow lives through time show that personality traits rival socioeconomic status and cognitive ability as predictors of mortality, divorce, and occupational attainment (Roberts et al., 2007).

Any of these tendencies, taken to either extreme, become maladaptive. Agreeableness ranges from cynical combativeness at its low extreme to gullible subservience at its high extreme. Conscientiousness ranges from irresponsible negligence to workaholic perfectionism (Widiger & Costa, 2012).

Although our personality *traits* may be both stable and potent, the consistency of our specific *behaviors* from one situation to the next is another matter. As Walter Mischel (1968, 2009) has pointed out, people do not act with predictable consistency. Mischel’s studies of college students’ conscientiousness revealed but a modest relationship between a student’s being conscientious on one occasion (say, showing up for class on time) and being similarly conscientious on another occasion (say, turning in assignments on time). If you’ve noticed how outgoing you are in some situations and how reserved you are in others, perhaps you’re not surprised (though for certain traits, Mischel reports, you may accurately assess yourself as more consistent).

This inconsistency in behaviors also makes personality test scores weak predictors of behaviors. People’s scores on an extraversion test, for example, do not neatly predict how sociable they actually will be on any given occasion. If we remember this, says Mischel, we will be more cautious about labeling and pigeonholing individuals. Years in advance, science can tell us the phase of the Moon for any given date. A day in advance, meteorologists can often predict the weather. But we are much further from being able to predict how *you* will feel and act tomorrow.

However, people’s *average* outgoingness, happiness, or carelessness over many situations is predictable (Epstein, 1983a,b). People who know someone well, therefore, generally agree when rating that person’s shyness or agreeableness (Kenrick & Funder, 1988). By collecting snippets of people’s daily experience via body-worn recording devices, Matthias Mehl and his colleagues (2006) confirmed that extraverts really do talk more. A similar extraversion-talkativeness relationship was also found among Bolivian hunter-gathers

It’s not just personality that stabilizes with age.

my hair over time

(Gurven et al., 2013). (I [DM] have repeatedly vowed to cut back on my jabbering and joking during my noontime pickup basketball games with friends. Alas, moments later, the irrepressible chatterbox inevitably reoccupies my body. And I [ND] have a similar experience each time I try to stay quiet in taxis. Somehow, I always end up chatting with the driver!) As our best friends can verify, we do have genetically influenced personality traits. And those traits even lurk, report Samuel Gosling and his colleagues in a series of studies, in our

- *music preferences.* Your playlist says a lot about your personality. Classical, jazz, blues, and folk music lovers tend to be open to experience and verbally intelligent. Extraverts tend to prefer upbeat and energetic music. Country, pop, and religious music lovers tend to be cheerful, outgoing, and conscientious (Langmeyer et al., 2012; Rentfrow & Gosling, 2003, 2006).
- *bedrooms and offices.* Our personal spaces display our identity and leave a behavioral residue (in our scattered laundry or neat desktop). After just a few minutes' inspection of our living and working spaces, a visitor could give a fairly accurate summary of our conscientiousness, our openness to new experiences, and even our emotional stability (Gosling et al., 2002, 2008).
- *online spaces.* Is a personal website, social media profile, or instant messaging account also a canvas for self-expression? Or is it an opportunity for people to present themselves in false or misleading ways? It's more the former (Back et al., 2010; Gosling et al., 2007; Marcus et al., 2006). Viewers quickly gain important clues to the creator's extraversion, conscientiousness, and openness to experience. Even mere pictures of people, and their associated clothes, expressions, and postures, can give clues to personality (Naumann et al., 2009).
- *written communications.* If you have ever felt you could detect someone's personality from their writing voice, you are right!! (What a cool, exciting finding!!! . . . if you catch our drift.) People's ratings of others' personalities based solely on what they've written correlate with actual personality scores on measures such as extraversion and neuroticism (Gill et al., 2006; Oberlander & Gill, 2006; Pennebaker, 2011; Yarkoni, 2010). Extraverts, for example, use more adjectives.

In unfamiliar, formal situations—perhaps as a guest in the home of a person from another culture—our traits remain hidden as we carefully attend to social cues. In familiar, informal situations—just hanging out with friends—we feel less constrained, allowing our traits to emerge (Buss, 1989). In these informal situations, our expressive styles—our animation, manner of speaking, and gestures—are impressively consistent. Viewing “thin slices” of someone's behavior—such as seeing a photo for a mere fraction of a second or seeing three 2-second video clips of a teacher in action—can tell us a lot about the person's basic personality traits (Ambady, 2010; Rule et al., 2009).

Some people are naturally expressive (and therefore talented at pantomime and charades); others are less expressive (and therefore better poker players). To evaluate people's voluntary control over their expressiveness, Bella DePaulo and her colleagues (1992) asked people to *act* as expressive or inhibited as possible while stating opinions. Their remarkable findings: Inexpressive people, even when feigning expressiveness, were less expressive than expressive people acting naturally. Similarly, expressive people, even when trying to seem inhibited, were less inhibited than inexpressive people acting naturally. It's hard to be someone you're not, or not to be who you are.

To sum up, we can say that at any moment the immediate situation powerfully influences a person's behavior. Social psychologists have learned that this is especially so when a “strong situation” makes clear demands (Cooper & Withey, 2009). We can better predict drivers' behavior at traffic lights from knowing the color of the lights than from knowing the drivers' personalities. Thus, professors may perceive certain

students as subdued (based on their classroom behavior), but friends may perceive them as pretty wild (based on their party behavior). Averaging our behavior across many occasions does, however, reveal distinct personality traits. Traits exist. We differ. And our differences matter.

RETRIEVAL PRACTICE

- How well do personality test scores predict our behavior? Explain.

ANSWER: Our scores on personality tests predict our *average* behavior across many situations much better than they predict our specific behavior in any given situation.

REVIEW Humanistic Theories and Trait Theories

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

14-10 How did humanistic psychologists view personality, and what was their goal in studying personality?

14-11 How did humanistic psychologists assess a person's sense of self?

14-12 How have humanistic theories influenced psychology? What criticisms have they faced?

14-13 How do psychologists use traits to describe personality?

14-14 What are some common misunderstandings about introversion? Does extraversion lead to greater success than introversion?

14-15 What are personality inventories, and what are their strengths and weaknesses as trait-assessment tools?

14-16 Which traits seem to provide the most useful information about personality variation?

14-17 Does research support the consistency of personality traits over time and across situations?

Social-Cognitive Theories and the Self

Social-Cognitive Theories

14-18 How do social-cognitive theorists view personality development, and how do they explore behavior?

Today's psychological science views individuals as biopsychosocial organisms. The **social-cognitive perspective** on personality proposed by Albert Bandura (1986, 2006, 2008) emphasizes the interaction of our traits with our situations. Much as nature and nurture always work together, so do individuals and their situations.

social-cognitive perspective views behavior as influenced by the interaction between people's traits (including their thinking) and their social context.

Social-cognitive theorists believe we learn many of our behaviors either through conditioning or by observing and imitating others. (That's the "social" part.) They also emphasize the importance of mental processes: What we *think* about a situation affects our resulting behavior. (That's the "cognitive" part.) Instead of focusing solely on how our environment *controls* us (behaviorism), social-cognitive theorists focus on how we and our environment *interact*: How do we interpret and respond to external events? How do our schemas, our memories, and our expectations influence our behavior patterns?

reciprocal determinism the interacting influences of behavior, internal cognition, and environment.

Reciprocal Influences

Bandura (1986, 2006) views the person-environment interaction as **reciprocal determinism**. "Behavior, internal personal factors, and environmental influences," he said, "all operate as interlocking determinants of each other" (FIGURE 14.5). We can see this interaction in the habits people develop in relationships. For example, Romena's history of romantic relationships (past behavior) influences her attitudes toward relationships in general (internal factor), which changes how she now responds to Ryan (environmental factor).

Consider three specific ways in which individuals and environments interact:

1. **Different people choose different environments.** The schools we attend, the reading we do, the movies we watch, the music we listen to, the friends we associate with—all are part of an environment we have chosen, based partly on our disposition (Funder, 2009; Ickes et al., 1997). We choose our environment and it then shapes us.
2. **Our personalities shape how we interpret and react to events.** Anxious people tend to attend and react strongly to relationship threats (Campbell & Marshall, 2011). If we perceive the world as threatening, we will watch for threats and be prepared to defend ourselves.
3. **Our personalities help create situations to which we react.** How we view and treat people influences how they then treat us. If we expect that others will not like us, our desperate attempts to seek their approval might cause them to reject us. Depressed people often engage in this excessive reassurance seeking, which confirms their negative self-views (Coyne, 1976a,b).

In addition to the interaction of internal personal factors, the environment, and our behaviors, we also experience *gene-environment interaction* (Chapter 4). Our genetically influenced traits evoke certain responses from others, which may nudge us in one direction or another. In one classic study, those with the interacting factors of (1) having a specific gene associated with aggression and (2) being raised in a difficult environment were most likely to demonstrate adult antisocial behavior (Caspi et al., 2002).

▼ **FIGURE 14.5**
Reciprocal determinism

In such ways, we are both the products and the architects of our environments: *Behavior emerges from the interplay of external and internal influences.* Boiling water turns an egg hard and a potato soft. A threatening environment turns one person into a hero, another into a scoundrel. Extraverts enjoy greater well-being in an extraverted culture than in an introverted one (Fulmer et al., 2010). *At every moment*, our behavior is influenced by our biology, our social and cultural experiences, and our cognition and dispositions (FIGURE 14.6).

RETRIEVAL PRACTICE

- Albert Bandura proposed the _____ - _____ perspective on personality, which emphasizes the interaction of people with their environment. To describe the interacting influences of behavior, thoughts, and environment, he used the term _____.

ANSWERS: social-cognitive; reciprocal determinism

Assessing Behavior in Situations

To predict behavior, social-cognitive psychologists often observe behavior in realistic situations. One ambitious example was the U.S. Army's World War II strategy for assessing candidates for spy missions. Rather than using paper-and-pencil tests, Army psychologists subjected the candidates to simulated undercover conditions. They tested their ability to handle stress, solve problems, maintain leadership, and withstand intense interrogation without blowing their cover. Although time-consuming and expensive, this assessment of behavior in a realistic situation helped predict later success on actual spy missions (OSS Assessment Staff, 1948). Modern studies indicate that assessment center exercises are more revealing of visible dimensions, such as communication ability, than others, such as inner achievement drive (Bowler & Woehr, 2006).

Assessing behavior in situations Reality TV shows, such as Donald Trump's *The Apprentice*, may take "show me" job interviews to the extreme, but they do illustrate a valid point. Seeing how a potential employee behaves in a job-relevant situation helps predict job performance.

Jennifer Szymaszek/AP Photo

Military and educational organizations and many Fortune 500 companies have adopted assessment center strategies (Bray et al., 1991, 1997; Eurich et al., 2009). AT&T has observed prospective managers doing simulated managerial work. Many colleges assess students' potential via internships and student teaching, and assess potential faculty members' teaching abilities by observing them teach. Most American cities with populations of 50,000 or more have used assessment centers in evaluating police officers and firefighters (Lowry, 1997).

These procedures exploit the principle that the best means of predicting future behavior is neither a personality test nor an interviewer's intuition. Rather, it is *the person's past behavior patterns in similar situations* (Lyons et al., 2011; Mischel, 1981; Schmidt & Hunter, 1998). As long as the situation and the person remain much the same, the best predictor of future job performance is past job performance; the best predictor of future grades is past grades; the best predictor of future aggressiveness is past aggressiveness. If you can't check the person's past behavior, the next best thing is to create an assessment situation that simulates the task so you can see how the person handles it (Lievens et al., 2009; Meriac et al., 2008).

“What's past is prologue.”

William Shakespeare, *The Tempest*, 1611

Evaluating Social-Cognitive Theories

14-19 What criticisms have social-cognitive theorists faced?

Social-cognitive theories of personality sensitize researchers to how situations affect, and are affected by, individuals. More than other personality theories (see TABLE 14.4), they build from psychological research on learning and cognition.

▼ TABLE 14.4
Comparing the Major Personality Theories

Personality Theory	Key Proponents	Assumptions	View of Personality	Personality Assessment Methods
<i>Psychoanalytic</i>	Freud	Emotional disorders spring from unconscious dynamics, such as unresolved sexual and other childhood conflicts, and fixation at various developmental stages. Defense mechanisms fend off anxiety.	Personality consists of pleasure-seeking impulses (the id), a reality-oriented executive (the ego), and an internalized set of ideals (the super-ego).	Free association, projective tests, dream analysis
<i>Psychodynamic</i>	Adler, Horney, Jung	The unconscious and conscious minds interact. Childhood experiences and defense mechanisms are important.	The dynamic interplay of conscious and unconscious motives and conflicts shape our personality.	Projective tests, therapy sessions
<i>Humanistic</i>	Rogers, Maslow	Rather than examining the struggles of sick people, it's better to focus on the ways healthy people strive for self-realization.	If our basic human needs are met, people will strive toward self-actualization. In a climate of unconditional positive regard, we can develop self-awareness and a more realistic and positive self-concept.	Questionnaires, therapy sessions
<i>Trait</i>	Allport, Eysenck, McCrae, Costa	We have certain stable and enduring characteristics, influenced by genetic predispositions.	Scientific study of traits has isolated important dimensions of personality, such as the Big Five traits (conscientiousness, agreeableness, neuroticism, openness, and extraversion).	Personality inventories
<i>Social-Cognitive</i>	Bandura	Our traits and the social context interact to produce our behaviors.	Conditioning and observational learning interact with cognition to create behavior patterns.	Our behavior in one situation is best predicted by considering our past behavior in similar situations.

self in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions.

spotlight effect overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us).

Critics charge that social-cognitive theories focus so much on the situation that they fail to appreciate the person's inner traits. Where is the person in this view of personality, ask the dissenters, and where are human emotions? True, the situation does guide our behavior. But, say the critics, in many instances our unconscious motives, our emotions, and our pervasive traits shine through. Personality traits have been shown to predict behavior at work, love, and play. Our biologically influenced traits really do matter. Consider Percy Ray Pridgen and Charles Gill. Each faced the same situation: They had jointly won a \$90 million lottery jackpot (Harriston, 1993). When Pridgen learned of the winning numbers, he began trembling uncontrollably, huddled with a friend behind a bathroom door while confirming the win, then sobbed. When Gill heard the news, he told his wife and then went to sleep.

RETRIEVAL PRACTICE

- What is the best way to predict a person's future behavior?

ANSWER: Examine the person's past behavior patterns in similar situations.

Exploring the Self

14-20 Why has psychology generated so much research on the self? How important is self-esteem to psychology and to human well-being?

Psychology's concern with people's sense of self dates back at least to William James, who devoted more than 100 pages of his 1890 *Principles of Psychology* to the topic. By 1943, Gordon Allport lamented that the self had become "lost to view." Although humanistic psychology's later emphasis on the self did not instigate much scientific research, it did help renew the concept of self and keep it alive. Now, more than a century after James, the self is one of Western psychology's most vigorously researched topics. Every year, new studies galore appear on self-esteem, self-disclosure, self-awareness, self-schemas, self-monitoring, and so forth. Even neuroscientists have searched for the self, by identifying a central frontal lobe region that activates when people respond to self-reflective questions about their traits and dispositions (Damasio, 2010; Mitchell, 2009; Pauly et al., 2013). Underlying this research is an assumption that the **self**, as organizer of our thoughts, feelings, and actions, is the center of personality.

One example of thinking about self is the concept of *possible selves* put forth by Hazel Markus and her colleagues (Cross & Markus, 1991; Markus & Nurius, 1986). Your possible selves include your visions of the self you dream of becoming—the rich self, the successful self, the loved and admired self. Your possible selves also include the self you fear becoming—the unemployed self, the academically failed self, the lonely and unpopular self. Possible selves motivate us to lay out specific goals that direct our energy effectively and efficiently (Landau et al., 2014). High school students enrolled in a gifted program for math and science were more likely to become scientists if they had a clear vision of themselves as successful scientists (Buday et al., 2012). Dreams do often give birth to achievements.

Our self-focused perspective may motivate us, but it can also lead us to presume too readily that others are noticing and evaluating us. Thomas Gilovich (1996) demonstrated this **spotlight effect** by having individual Cornell University students don Barry Manilow T-shirts before entering a room with other students. Feeling self-conscious, the T-shirt wearers guessed that nearly half their peers would take note of the shirt as they walked in. In reality, only 23 percent did. This

"The first step to better times is to imagine them."

Trinity Mirror/
Mirrorpix/Alamy

absence of attention applies not only to our dorky clothes and bad hair but also to our nervousness, irritation, or attraction: Fewer people notice than we presume (Gilovich & Savitsky, 1999). Others are also less aware than we suppose of the variability—the ups and downs—of our appearance and performance (Gilovich et al., 2002). Even after a blunder (setting off a library alarm, showing up in the wrong clothes), we stick out like a sore thumb less than we imagine (Savitsky et al., 2001). To turn down the brightness of the spotlight, we can use two strategies. The first is simply knowing about the spotlight effect. Public speakers who understand that their natural nervousness is not obvious perform better (Savitsky & Gilovich, 2003). The second is to take the audience's perspective. When we imagine audience members empathizing with our situation, we tend to expect we will not be judged as harshly (Epley et al., 2002).

The Benefits of Self-Esteem

How we feel about ourselves is also important. High **self-esteem**—our feelings of self-worth—pays dividends. So also does **self-efficacy**, our sense of competence on a task. People who feel good about themselves (who strongly agree with self-affirming questionnaire statements such as, “I am fun to be with”) have fewer sleepless nights. They succumb less easily to pressures to conform. They make more positive Facebook posts, causing others to like them more (Forest & Wood, 2012). They are more persistent at difficult tasks; they are less shy, anxious, and lonely. And they are just plain happier (Greenberg, 2008; Orth et al., 2008, 2009). If feeling bad, they think they deserve better and thus make more effort to repair their mood (Wood et al., 2009).

But is high self-esteem the horse or the cart? Is it really “the armor that protects kids” from life's problems (McKay, 2000)? Some psychologists have their doubts (Baumeister, 2006; Dawes, 1994; Leary, 1999; Seligman, 1994, 2002). Children's academic self-efficacy—their confidence that they can do well in a subject—predicts school achievement. But general self-image does not (Marsh & Craven, 2006; Swann et al., 2007; Trautwein et al., 2006). Maybe self-esteem simply reflects reality. Maybe it's a side effect of meeting challenges and surmounting difficulties. Maybe self-esteem is a gauge that reads out the state of our relationships with others. If so, isn't pushing the gauge artificially higher with empty compliments much like forcing a car's low fuel gauge to display “full”?

If feeling good *follows* doing well, then giving praise in the absence of good performance may actually harm people. After receiving weekly self-esteem-boosting messages, struggling students earned *lower*-than-expected grades (Forsyth et al., 2007). Other research showed that giving people random rewards hurt their productivity. Martin Seligman reported that “when good things occurred that weren't earned, like nickels coming out of slot machines, it did not increase people's well-being. It produced helplessness. People gave up and became passive.”

Experiments do reveal an *effect* of low self-esteem. Temporarily deflate people's self-image (say, by telling them they did poorly on an aptitude test or by disparaging their personality) and they will be more likely to disparage others or to express heightened racial prejudice (vanDellen et al., 2011; Van Dijk et al., 2011; Ybarra, 1999). Self-image threat even increases unconscious racial bias (Allen & Sherman, 2011). Those who are negative about themselves have also tended to be oversensitive and judgmental (Baumgardner et al., 1989; Pelham, 1993). In experiments, people made to feel insecure have often become excessively critical, as if to impress others with their own brilliance (Amabile, 1983). Self-esteem threats also lead people to gravitate toward their online profiles—safe havens in which to rebuild their self-worth (Toma & Hancock, 2013). Such findings are consistent with humanistic psychology's presumption that a healthy self-image is essential. Accept yourself and you'll find it easier to accept others.

self-esteem one's feelings of high or low self-worth.

self-efficacy one's sense of competence and effectiveness.

“When kids increase in self-control, their grades go up later. But when kids increase their self-esteem, there is no effect on their grades.”

Angela Duckworth,
In *Character* interview, 2009

Disparage yourself and you will be prone to the floccinaucinihilipilification¹ of others. Said more simply, some “love their neighbors as themselves”; others loathe their neighbors as themselves. People who are down on themselves tend to be down on others.

Costs of Self-Esteem

14-21 How do excessive optimism, blindness to one’s own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

Excessive Optimism Positive thinking in the face of adversity can pay dividends, but so, too, can a dash of realism (Schneider, 2001). Realistic anxiety over possible future failures can fuel energetic efforts to avoid the dreaded fate (Goodhart, 1986; Norem, 2001; Showers, 1992). Concerned about failing an upcoming exam, students may study thoroughly and outperform their equally able but more confident peers. Asian-American students have expressed somewhat greater pessimism than their European-American counterparts, which may help explain their often impressive academic achievements (Chang, 2001). Success requires enough optimism to provide hope and enough pessimism to prevent complacency. We want our airline pilots to be mindful of worst-possible outcomes.

Excessive optimism can blind us to real risks. Neil Weinstein (1980, 1982, 1996) has shown how our natural positive thinking bias can promote “an unrealistic optimism about future life events.” Most college students perceive themselves as less likely than their average classmate to develop drinking problems, drop out of school, have a heart attack by age 40, or go deeply into debt on their high-interest credit cards (Yang et al., 2006). When people entertain positive fantasies about financial success or travel adventure, they often focus on the rewards and ignore the risks (Kappes & Oettingen, 2012). If overconfident of our ability to control an impulse such as the urge to smoke, we are more likely to expose ourselves to temptations—and to fail (Nordgren et al., 2009). Those who optimistically deny the power and effects of smoking, venture into ill-fated relationships, and outwit themselves in dozens of other ways remind us that blind optimism can be self-defeating.

People also display illusory optimism about their groups. Throughout a National Football League season, fans of all teams correctly guessed that other teams would win about 50 percent of their games. But they incorrectly guessed, on average (across teams and weeks), that their own team stood about a 2 in 3 chance of winning (Massey et al., 2011). This optimistic and illogical bias persisted despite their team’s experience and monetary incentives for accuracy.

Our natural positive thinking bias does seem to vanish, however, when we are bracing ourselves for feedback, such as exam results (Carroll et al., 2006). In one analysis of 71 studies, most people shifted their expectations downward shortly before the moment of truth (Sweeny & Krizan, 2013). Positive illusions also vanish after a traumatic personal experience—as they did for victims of a catastrophic California earthquake, who had to give up their illusions of being less vulnerable than others to earthquakes (Helweg-Larsen, 1999).

Blindness to One’s Own Incompetence Ironically, people often are most overconfident when most incompetent. That, say Justin Kruger and David Dunning (1999), is because it often takes competence to recognize competence. They found

1. We couldn’t resist throwing that in. But don’t worry, you won’t be tested on floccinaucinihilipilification, which is the act of estimating something as worthless (and was the longest nontechnical word in the first edition of the *Oxford English Dictionary*).

that most students scoring at the low end of grammar and logic tests believed they had scored in the top half. If you do not know what good grammar is, you may be unaware that your grammar is poor. This “ignorance of one’s own incompetence” phenomenon has a parallel, as I [DM] can confirm, in hard-of-hearing people’s difficulty recognizing their own hearing loss. We’re not so much “in denial” as we are simply unaware of what we don’t hear. If I fail to hear my friend calling my name, the friend notices my inattention. But for me it’s a nonevent. I hear what I hear—which, to me, seems pretty normal.

The difficulty in recognizing one’s own incompetence helps explain why so many low-scoring students are dumbfounded after doing badly on an exam. If you don’t know all the Scrabble word possibilities you’ve overlooked, you may feel pretty smart—until they are pointed out. Our ignorance of what we don’t know sustains our self-confidence, leading us to make the same mistakes (Williams et al., 2013).

To judge one’s competence and predict one’s future performance, it pays to invite others’ assessments, notes Dunning (2006). Based on studies in which both individuals and their acquaintances predict their future, we can hazard some advice: If you’re a junior doctor and want to predict how well you will do on a surgical skills exam, don’t rate yourself—ask your peers for their candid prediction. If you’re a naval officer and need to assess your leadership ability—don’t rate yourself, ask your fellow officers. And if you’re in love and want to predict whether it will last, don’t listen to your heart—ask your roommate.

Self-Serving Bias Imagine dashing to class, hoping not to miss the first few minutes. But you arrive five minutes late, huffing and puffing. As you sink into your seat, what sorts of thoughts go through your mind? Do you go through a negative door, with thoughts such as, “I hate myself” and “I’m a loser”? Or do you go through a positive door, saying to yourself, “At least I made it to class” and “I really tried to get here on time”?

Personality psychologists have found that most people choose the second door, which leads to positive self-thoughts. We have a good reputation with ourselves. We show a **self-serving bias**—a readiness to perceive ourselves favorably (Myers, 2010). Consider:

People accept more responsibility for good deeds than for bad, and for successes than for failures. Athletes often privately credit their victories to their own prowess, and their losses to bad breaks, lousy officiating, or the other team’s exceptional performance.

self-serving bias a readiness to perceive oneself favorably.

Most students who receive poor grades on an exam criticize the exam, not themselves. Drivers filling out insurance forms have explained their accidents in such words as “A pedestrian hit me and went under my car.” The question “What have I done to deserve this?” is one we usually ask of our troubles, not our successes. Although a self-serving bias can lead us to avoid uncomfortable truths, it can also motivate us to approach difficult tasks with confidence instead of despair (Tomaka et al., 1992; von Hippel & Trivers, 2011).

Most people see themselves as better than average. Compared with most other people, how nice are you? How easy to get along with? How appealing are you as a friend or romantic partner? Where would you rank yourself from the 1st to the 99th percentile? Most people put themselves well above the 50th percentile. This better-than-average effect appears for nearly any subjectively assessed and socially desirable behavior:

- In national surveys, most business executives say they are more ethical than their average counterpart. In several studies, 90 percent of business managers and more than 90 percent of college professors also rated their performance as superior to that of their average peer.
- In Australia, 86 percent of people rate their job performance as above average, and only 1 percent as below average.
- In the National Survey of Families and Households, 49 percent of men said they provided half or more of the child care, though only 31 percent of their wives or partners saw things that way (Galinsky et al., 2008).
- Brain scans reveal that the more people judge themselves as better than average, the less brain activation they show in regions that aid careful self-reflection (Beer & Hughes, 2010). It seems our brain’s default setting is to think we are better than others.

PEANUTS

The phenomenon, which reflects overestimating the self as well as the desire to maintain a positive self-view (Brown, 2012; Epley & Dunning, 2000), is less striking in Asia, where people value modesty (Falk et al., 2009; Heine & Hamamura, 2007). Yet self-serving biases have been observed worldwide: In every one of 53 countries surveyed, people expressed self-esteem above the midpoint of the most widely used scale (Schmitt & Allik, 2005).

Ironically, people even see themselves as more immune than others to self-serving bias (Pronin, 2007). That’s right, people believe they are above average at not believing they are above average. (Isn’t psychology fun?) The world, it seems, is Garrison Keillor’s Lake Wobegon writ large—a place where “all the women are strong, all the men are good-looking, and all the children are above average.”

Self-serving bias flies in the face of pop psychology. “All of us have inferiority complexes,” wrote John Powell (1989, p. 15). “Those who seem not to have such a complex are only pretending.” But additional findings remove any doubts (Guenther & Alicke, 2010; Koudenburg et al., 2011; Myers, 2010):

“If you are like most people, then like most people, you don’t know you’re like most people. Science has given us a lot of facts about the average person, and one of the most reliable of these facts is the average person doesn’t see herself as average.”

Daniel Gilbert, *Stumbling on Happiness*, 2006

TOO MUCH COFFEE MAN BY SHANNON WHEELER

- We remember and justify our past actions in self-enhancing ways, and exhibit an inflated confidence in our beliefs and judgments. We are quicker to believe flattering descriptions of ourselves than unflattering ones, and we are impressed with psychological tests that make us look good.
- In situations where most people behave less than admirably, we overestimate how desirably we would act. We shore up our self-image by overestimating the commonality of our foibles and by underestimating the commonality of our strengths.
- We see ourselves making better-than-average contributions to our groups (but so do our teammates, which explains why group members' self-contribution estimates usually total more than 100 percent).
- We exhibit group pride—a tendency to see our group (our school, our country, even our pets) as superior.

Authentic pride that's rooted in actual achievement supports self-confidence and leadership (Tracy et al., 2009; Williams & DeSteno, 2009). Yet self-serving perceptions underlie conflicts ranging from blaming one's spouse for marital discord to arrogantly promoting one's own ethnic superiority. These self-serving tendencies may also explain why people attribute less responsibility for their group's violent actions (Bilali et al., 2012). Finding their self-esteem threatened, people with large egos may react violently. "Aryan pride" fueled Nazi atrocities. "These biases have the effect of making wars more likely to begin and more difficult to end," noted Daniel Kahneman and Jonathan Renshon (2007).

We can see these tendencies even in children, where the recipe for frequent fighting mixes high self-esteem with social rejection. The most aggressive children tend to have high self-regard that gets punctured by other kids' dislike (van Boxtel et al., 2004). Similarly, an adolescent or adult with a swelled head that gets deflated by an insult is potentially dangerous. Brad Bushman and Roy Baumeister (1998; Bushman et al., 2009) experimented with this "dark side of high self-esteem." They had 540 undergraduate volunteers write a brief essay, in response to which another supposed student gave

"The [self]portraits that we actually believe, when we are given freedom to voice them, are dramatically more positive than reality can sustain."

Shelley Taylor, *Positive Illusions*, 1989

them either praise (“Great essay!”) or stinging criticism (“One of the worst essays I have read!”). Then the essay writers played a reaction-time game against the other student. After wins, they could assault their opponent with noise of any intensity for any duration.

Can you anticipate the result? After criticism, those with inflated high self-esteem were “exceptionally aggressive.” They delivered three times the auditory torture of those with normal self-esteem. Threatened egotism, more than low self-esteem, it seems, predisposes aggression. “Encouraging people to feel good about themselves when they haven’t earned it” poses problems, Baumeister (2001) concluded. “Conceited, self-important individuals turn nasty toward those who puncture their bubbles of self-love.”

From 1980 to 2007, popular song lyrics became more self-focused (DeWall et al., 2011). An analysis of 766,513 American books published between 1960 and 2008 showed a similar result: Self-focused words increased (Twenge et al., 2013). On one prominent self-esteem inventory on which 40 is the highest possible self-esteem score, 51 percent of 2008 collegians scored 35 or more (Gentile et al., 2010). Another statistical synopsis—of over 9 million high school seniors and entering college students between 1966 and 2009—also found interest in gaining money, fame, and prestige increasing and concern for others decreasing (Twenge et al., 2012).

After tracking self-importance across the last several decades, psychologist Jean Twenge (2006; Twenge & Foster, 2010) reports that what she calls *Generation Me* expresses more **narcissism** (by agreeing more often with statements such as, “If I ruled the world, it would be a better place,” or “I think I am a special person”). Agreement with such narcissistic statements correlates with materialism, the desire to be famous, inflated expectations, more hookups with fewer committed relationships, more gambling, and more cheating, all of which have been on the rise as narcissism has increased. *Narcissistic* people forgive others less, take a game-playing approach to their romantic relationships, and make poor leaders (Campbell et al., 2002; Exline et al., 2004; Nevicka et al., 2011). Hollywood actors and reality television stars—at least those appearing on one national radio show who agreed to take the narcissism test anonymously—are especially narcissistic (Young & Pinsky, 2006). At the collective level, narcissism (sample item: “My group is extraordinary”) predicts increased sensitivity to threats and retaliatory aggression (de Zavala et al., 2009; Lyons et al., 2013).

Despite the demonstrated perils of pride, many people object that the idea of self-serving bias overlooks those who feel worthless and unlovable. If self-serving bias prevails, why do so many people disparage themselves? For four reasons: Sometimes self-directed put-downs are *subtly strategic*: They elicit reassuring strokes. Saying “No one likes me” may at least elicit “But not everyone has met you!” Other times, such as before a game or an exam, self-disparaging comments *prepare us for possible failure*. The coach who extols the superior strength of the upcoming opponent makes a loss understandable, a victory noteworthy. A self-disparaging “How could I have been so stupid!” also helps us *learn from our mistakes*. And finally, self-disparagement also frequently *pertains to one’s old self*. Asked to remember their really bad behaviors, people recall things from long ago; good behaviors more easily come to mind from their recent past (Escobedo & Adolphs, 2010). People are much more critical of their distant past selves than of their current selves—even when they have not changed (Wilson & Ross, 2001). “At 18, I was a jerk; today I’m more sensitive.” In their own eyes, chumps yesterday, champs today.

Even so, it’s true: All of us some of the time, and some of us much of the time, do feel inferior—especially when we compare ourselves with those who are a step or two higher on the ladder of status, looks, income, or ability. For example, Olympians who

“The enthusiastic claims of the self-esteem movement mostly range from fantasy to hogwash. The effects of self-esteem are small, limited, and not all good.”

Roy Baumeister (1996)

“If you compare yourself with others, you may become vain and bitter; for always there will be greater and lesser persons than yourself.”

Max Ehrmann, “Desiderata,” 1927

win silver medals, barely missing gold, show greater sadness on the awards podium compared with the bronze medal winners (Medvec et al., 1995). The deeper and more frequently we have such feelings, the more unhappy, even depressed, we are. But for most people, thinking has a naturally positive bias.

While recognizing the dark side of self-serving bias and self-esteem, some researchers prefer isolating the effects of two types of self-esteem—defensive and secure (Kernis, 2003; Lambird & Mann, 2006; Ryan & Deci, 2004). *Defensive self-esteem* is fragile. It focuses on sustaining itself, which makes failure and criticism feel threatening. Such egotism exposes one to perceived threats, which feed anger and feelings of vulnerability, notes Jennifer Crocker (2011).

Secure self-esteem is less fragile, because it is less contingent on external evaluations. To feel accepted for who we are, and not for our looks, wealth, or acclaim, relieves pressures to succeed and enables us to focus beyond ourselves. By losing ourselves in relationships and purposes larger than self, Crocker adds, we may achieve a more secure self-esteem, satisfying relationships, and greater quality of life.

narcissism excessive self-love and self-absorption.

RETRIEVAL PRACTICE

- What are the positive and negative effects of high self-esteem?
ANSWER: People who feel confident in their abilities are often happier, have greater motivation, and are less susceptible to depression. Excessive optimism and very high self-esteem can lead to blindness to one's own incompetence, self-serving bias, and narcissism.
- The tendency to accept responsibility for success and blame circumstances or bad luck for failures is called _____ - _____.
ANSWER: self-serving bias
- _____ (Secure/Defensive) self-esteem correlates with aggressive and antisocial behavior. _____ (Secure/Defensive) self-esteem is a healthier self-image that allows us to focus beyond ourselves and enjoy a higher quality of life.
ANSWERS: Defensive; Secure

REVIEW Social-Cognitive Theories and the Self

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

14-18 How do social-cognitive theorists view personality development, and how do they explore behavior?

14-19 What criticisms have social-cognitive theorists faced?

14-20 Why has psychology generated so much research on the self? How important is self-esteem to psychology and to human well-being?

14-21 How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

TERMS AND CONCEPTS TO REMEMBER

TEST YOURSELF

PERSONALITY

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Introduction to Personality and Psychodynamic Theories

- Freud believed that we may block painful or unacceptable thoughts, wishes, feelings, or memories from consciousness through an unconscious process called _____.
- According to Freud's view of personality structure, the "executive" system, the _____, seeks to gratify the impulses of the _____ in more acceptable ways.
 - id; ego
 - ego; superego
 - ego; id
 - id; superego
- Freud proposed that the development of the "voice of conscience" is related to the _____, which internalizes ideals and provides standards for judgments.
- According to the psychoanalytic view of development, we all pass through a series of psychosexual stages, including the oral, anal, and phallic stages. Conflicts unresolved at any of these stages may lead to
 - dormant sexual feelings.
 - fixation at that stage.
 - preconscious blocking of impulses.
 - a distorted gender identity.
- Freud believed that defense mechanisms are unconscious attempts to distort or disguise reality, all in an effort to reduce our _____.
- _____ tests ask test-takers to respond to an ambiguous stimulus, for example, by describing it or telling a story about it.
- In general, neo-Freudians such as Adler and Horney accepted many of Freud's views but placed more emphasis than he did on
 - development throughout the life span.
 - the collective unconscious.
 - the role of the id.
 - social interactions.

8. Modern-day psychodynamic theorists and therapists agree with Freud about
 - a. the existence of unconscious mental processes.
 - b. the Oedipus complex.
 - c. the predictive value of Freudian theory.
 - d. the superego's role as the executive part of personality.
9. Which of the following is NOT part of the contemporary view of the unconscious?
 - a. Repressed memories of anxiety-provoking events
 - b. Schemas that influence our perceptions and interpretations
 - c. Parallel processing that occurs without our conscious knowledge
 - d. Instantly activated emotions and implicit memories of learned skills

Humanistic Theories and Trait Theories

10. Maslow's hierarchy of needs proposes that we must satisfy basic physiological and safety needs before we seek ultimate psychological needs, such as self-actualization. Maslow based his ideas on
 - a. Freudian theory.
 - b. his experiences with patients.
 - c. a series of laboratory experiments.
 - d. his study of healthy, creative people.
11. How might Rogers explain how environment influences the development of a criminal?
12. The total acceptance Rogers advocated as part of a growth-promoting environment is called _____.
13. _____ theories of personality focus on describing characteristic behavior patterns, such as agreeableness or extraversion.
14. One famous personality inventory is the
 - a. Extraversion-Introversion Scale.
 - b. Person-Situation Inventory.
 - c. MMPI.
 - d. Rorschach.
15. Which of the following is NOT one of the Big Five personality factors?
 - a. Conscientiousness
 - b. Anxiety
 - c. Extraversion
 - d. Agreeableness
16. Our scores on personality tests best predict
 - a. our behavior on a specific occasion.
 - b. our average behavior across many situations.
 - c. behavior involving a single trait, such as conscientiousness.
 - d. behavior that depends on the situation or context.

Social-Cognitive Theories and the Self

17. The social-cognitive perspective proposes our personality is shaped by a process called reciprocal determinism, as personal factors, environmental factors, and behaviors interact. An example of an environmental factor is
 - a. the presence of books in a home.
 - b. a preference for outdoor play.
 - c. the ability to read at a fourth-grade level.
 - d. the fear of violent action on television.
18. Critics say that _____ - _____ personality theory is very sensitive to an individual's interactions with particular situations, but that it gives too little attention to the person's enduring traits.
19. Researchers have found that low self-esteem tends to be linked with life problems. How should this link be interpreted?
 - a. Life problems cause low self-esteem.
 - b. The answer isn't clear because the link is correlational and does not indicate cause and effect.
 - c. Low self-esteem leads to life problems.
 - d. Because of the self-serving bias, we must assume that external factors cause low self-esteem.
20. A fortune cookie advises, "Love yourself and happiness will follow." Is this good advice?
21. The tendency to overestimate others' attention to and evaluation of our appearance, performance, and blunders is called the _____.

Introduction to Psychological Disorders

Anxiety Disorders, OCD, and PTSD

Depressive Disorders and Bipolar Disorder

Schizophrenia

Dissociative, Personality, and Eating Disorders

PSYCHOLOGICAL DISORDERS

.....

I felt the need to clean my room at home in Indianapolis every Sunday and would spend four to five hours at it. I would take every book out of the bookcase, dust and put it back. At the time I loved doing it. Then I didn't want to do it anymore, but I couldn't stop. The clothes in my closet hung exactly two fingers apart. . . . I made a ritual of touching the wall in my bedroom before I went out because something bad would happen if I didn't do it the right way. I had a constant anxiety about it as a kid, and it made me think for the first time that I might be nuts.

Marc, diagnosed with obsessive-compulsive disorder (from Summers, 1996)

Whenever I get depressed it's because I've lost a sense of self. I can't find reasons to like myself. I think I'm ugly. I think no one likes me. . . . I become grumpy and short-tempered. Nobody wants to be around me. I'm left alone. Being alone confirms that I am ugly and not worth being with. I think I'm responsible for everything that goes wrong.

Greta, diagnosed with depression (from Thorne, 1993, p. 21)

Voices, like the roar of a crowd, came. I felt like Jesus; I was being crucified. It was dark. I just continued to huddle under the blanket, feeling weak, laid bare and defenseless in a cruel world I could no longer understand.

Stuart, diagnosed with schizophrenia (from Emmons et al., 1997)

Now and then, all of us feel, think, or act in ways that may resemble a psychological disorder. We feel anxious, depressed, withdrawn, or suspicious, just less intensely and more briefly. So it's no wonder that we are drawn to try to understand disturbed mental states—we sometimes see ourselves in the psychological disorders we study. "To study the abnormal is the best way of understanding the normal," said William James (1842–1910).

Another reason for our curiosity is that most of us will, at some point, encounter someone with a psychological disorder. Personally or through friends or family, we may experience the bewilderment and pain of unexplained physical symptoms, irrational fears, or a feeling that life is not worth living. In one study of 26 American college campuses, 32 percent of students reported an apparent mental health problem (Eisenberg et al., 2011).

Worldwide, some 450 million people live with mental or behavior disorders (WHO, 2010). Although their rates and symptoms vary by culture, no known society is free of two terrible disorders—major depression and schizophrenia (Baumeister & Härter, 2007; Draguns, 1990a,b, 1997). This chapter examines these disorders and others. Chapter 16 considers their *treatment*.

Introduction to Psychological Disorders

“Who in the rainbow can draw the line where the violet tint ends and the orange tint begins? Distinctly we see the difference of the colors, but where exactly does the one first blendingly enter into the other? So with sanity and insanity.”

Herman Melville, *Billy Budd, Sailor*, 1924

psychological disorder a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior.

Most people would agree that someone who is too depressed to get out of bed for weeks at a time has a psychological disorder. But what about those who, having experienced a loss, are unable to resume their usual social activities? Where should we draw the line between sadness and depression? Between zany creativity and bizarre irrationality? Between normality and abnormality? Let's start with these questions:

- How should we *define* psychological disorders?
- How should we *understand* disorders? How do underlying biological factors contribute to disorder? How do troubling environments influence our well-being? And how do these effects of nature and nurture interact?
- How should we *classify* psychological disorders? And can we do so in a way that allows us to help people without stigmatizing them with *labels*?
- What do we know about *rates* of psychological disorders? How many people have them? Who is vulnerable, and when?

Defining Psychological Disorders

15-1 How should we draw the line between normality and disorder?

A **psychological disorder** is a syndrome (collection of symptoms) marked by a “clinically significant disturbance in an individual's cognition, emotion regulation, or behavior” (American Psychiatric Association, 2013). Disturbed, or *dysfunctional* thoughts, emotions, or behaviors are *maladaptive*—they interfere with normal day-to-day life. Believing your home must be thoroughly cleaned every weekend is not a disorder. But if cleaning rituals interfere with work and leisure, as Marc's did in this chapter's opening, they may be signs of a disorder. And occasional sad moods that persist and become disabling may likewise signal a psychological disorder.

Distress often accompanies dysfunctional behaviors. Marc, Greta, and Stuart were all distressed by their behaviors or emotions.

Over time, definitions of what makes for a “significant disturbance” have varied. From 1952 through December 9, 1973, homosexuality was classified as a psychological disorder. By day's end on December 10, it was not. The American Psychiatric Association made this change because more and more of its members no longer viewed same-sex attraction as a psychological problem. Such is the power of shifting societal beliefs. (Later research revealed, however, that the *stigma and stresses* that gay, lesbian, and transsexual people often experience can increase the risk of mental health problems [Hatzenbuehler et al., 2009; Meyer, 2003].) In the twenty-first century, other controversies swirl over new or altered diagnoses (such as *attention-deficit/hyperactivity disorder*) in the most recent classification tool for describing disorders. (You'll hear more about this later.)

Culture and normality Young men of the West African Wodaabe tribe put on elaborate makeup and costumes to attract women. Young American men may buy flashy cars with loud stereos to do the same. Each culture may view the other's behavior as abnormal.

Carol Beckwith

RETRIEVAL PRACTICE

- A lawyer is distressed by feeling the need to wash his hands 100 times a day. He has no time left to meet with clients, and his colleagues are wondering about his competence. His behavior would probably be labeled disordered, because it is _____—that is, it interferes with his day-to-day life.

ANSWER: maladaptive

Understanding Psychological Disorders

15-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The way we view a problem influences how we try to solve it. In earlier times, people often viewed strange behaviors as evidence that strange forces—the movements of the stars, godlike powers, or evil spirits—were at work. Had you lived during the Middle Ages, you might have said “The devil made him do it.” Believing that, you might have approved of a cure that would drive out the evil demon. Thus, people considered “mad” were sometimes caged or given “therapies” such as genital mutilation, beatings, removal of teeth or lengths of intestines, or transfusions of animal blood (Farina, 1982). Barbaric treatments for mental illness linger even today. In some places, people are chained to a bed, locked in their rooms, or even locked in a room with wild hyenas, in the belief that the animals will see and attack evil spirits (Hooper, 2013). Noting the physical and emotional damage of such restraint, the World Health Organization launched a “chain-free initiative” that aims to reform hospitals “into patient-friendly and humane places with minimum restraints” (WHO, 2014).

The Medical Model

Brutal treatments may worsen, rather than improve, mental health. Reformers, such as Philippe Pinel (1745–1826) in France, opposed such brutal treatments. Madness is not demon possession, he insisted, but a sickness of the mind caused by severe stress and inhumane conditions. Curing the illness, he said, requires “moral treatment,” including boosting patients’ morale by unchaining them and talking with them. He and others worked to replace brutality with gentleness, isolation with activity, and filth with clean air and sunshine.

John W. Verano

Yesterday’s “therapy” Through the ages, psychologically disordered people have received brutal treatments, including the trephination evident in this Stone Age skull. Drilling skull holes like these may have been an attempt to release evil spirits and cure those with mental disorders. Did this patient survive the “cure”?

Bellows, George Wesley (1882–1925)/San Diego Museum of Art, USA/Museum Purchase The Bridgeman Art Library

“Moral treatment” Under Philippe Pinel’s influence, hospitals sometimes sponsored patient dances, often called “lunatic balls,” depicted in this painting by George Bellows (*Dance in a Madhouse*).

medical model the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed*, *treated*, and, in most cases, *cured*, often through treatment in a *hospital*.

epigenetics the study of environmental influences on gene expression that occur without a DNA change.

By the 1800s, the discovery that syphilis infects the brain and distorts the mind drove further gradual reform. Hospitals replaced asylums, and the **medical model** of mental disorders was born. This model is reflected in the terms we still use today. We speak of the mental *health* movement: A mental *illness* (also called a *psychopathology*) needs to be *diagnosed* on the basis of its *symptoms*. It needs to be *treated* through *therapy*, which may include time in a psychiatric *hospital*.

The medical perspective has gained credibility from recent discoveries that genetically influenced abnormalities in brain structure and biochemistry contribute to many disorders. But as we will see, psychological factors, such as chronic or traumatic stress, also play an important role.

The Biopsychosocial Approach

To call psychological disorders “sicknesses” tilts research heavily toward the influence of biology and away from the influence of our personal histories and social and cultural surroundings. But in the study of disorders, as in so many other areas, we must remember that our behaviors, our thoughts, and our feelings are formed by the interaction of biological, psychological, and social-cultural influences. As individuals, we differ in the amount of stress we experience and in the ways we cope with stressors. Cultures also differ in their sources of stress and in traditional ways of coping.

Some disorders, such as depression and schizophrenia, occur worldwide. From Asia to Africa and across the Americas, schizophrenia’s symptoms often include irrationality and incoherent speech. Other disorders tend to be associated with specific cultures. In Malaysia, *amok* describes a sudden outburst of violent behavior (thus the English phrase “run amok”). Latin America lays claim to *susto*, a condition marked by severe anxiety, restlessness, and a fear of black magic. In Japanese culture, people may experience *taijin kyofusho*—social anxiety about their appearance, combined with a readiness to blush and a fear of eye contact. The eating disorders anorexia nervosa and bulimia nervosa occur mostly in food-abundant Western cultures. Such disorders may share an underlying dynamic (such as anxiety) while differing in the symptoms (an eating problem or a type of fear) manifested in a particular culture.

Disorders reflect genetic predispositions and physiological states, inner psychological dynamics, and social and cultural circumstances. The biopsychosocial approach emphasizes that mind and body are inseparable (FIGURE 15.1). Negative emotions contribute to physical illness, and physical abnormalities contribute to negative emotions. **Epigenetics**, the study of how nurture shapes nature, also informs our understanding of disorders (Powledge, 2011). Genes and environment are not the whole story, as we’ve seen in other chapters. It turns out our environment can affect whether a gene is *expressed* or not, and thus affect the development of various psychological disorders.

Increasingly, North America’s disorders, along with McDonald’s and MTV, have spread across the globe (Watters, 2010).

For example, even identical twins (with identical genes) do not share the same risks of developing psychological disorders. They are more likely, but not always destined, to develop the same disorders. Their varying environmental factors influence whether certain culprit genes are expressed.

RETRIEVAL PRACTICE

- Are psychological disorders universal, or are they culture-specific? Explain with examples.
- What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?

DSM-5 the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders.

Classifying Disorders—and Labeling People

15-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

In biology, classification creates order. To classify an animal as a “mammal” says a great deal—that it is warm-blooded, has hair or fur, and produces milk to nourish its young. In psychiatry and psychology, too, classification orders and describes symptoms. To classify a person’s disorder as “schizophrenia” suggests that the person talks incoherently, has bizarre beliefs, shows either little emotion or inappropriate emotion, or is socially withdrawn. “Schizophrenia” is a quick way to describe a complex disorder.

But diagnostic classification gives more than a thumbnail sketch of a person’s disordered behavior, thoughts, or feelings. In psychiatry and psychology, classification also aims to

- *predict* the disorder’s future course.
- *suggest* appropriate treatment.
- *prompt* research into its causes.

To study a disorder, we must first name and describe it.

The most common tool for describing disorders and estimating how often they occur is the American Psychiatric Association’s 2013 *Diagnostic and Statistical Manual of Mental Disorders*, now in its fifth edition (**DSM-5**). Physicians and mental health workers use the detailed “diagnostic criteria and codes” in the DSM-5 to guide medical diagnoses and treatment. For example, a person may be diagnosed with and treated for “insomnia disorder” if he or she meets *all* of the criteria in **TABLE 15.1**.

▼ **TABLE 15.1**
Insomnia Disorder

• Feeling unsatisfied with amount or quality of sleep (trouble falling asleep, staying asleep, or returning to sleep)
• Sleep disruption causes distress or diminished everyday functioning
• Happens three or more nights each week
• Occurs during at least three consecutive months
• Happens even with sufficient sleep opportunities
• Independent from other sleep disorders (such as narcolepsy)
• Independent from substance use or abuse
• Independent from other mental disorders or medical conditions

“I’m always like this, and my family was wondering if you could prescribe a mild depressant.”

A book of case illustrations accompanying the previous DSM edition provided several examples for this chapter.

In the DSM-5, some diagnostic labels have changed. The conditions formerly called “autism” and “Asperger’s syndrome” have now been combined under the label *autism spectrum disorder*. “Mental retardation” has become *intellectual disability*. New categories, such as *hoarding disorder* and *binge-eating disorder*, have been added.

Some of the new or altered diagnoses are controversial. *Disruptive mood dysregulation disorder* is a new DSM-5 diagnosis for children “who exhibit persistent irritability and frequent episodes of behavior outbursts three or more times a week for more than a year.” Will this diagnosis assist parents who struggle with unstable children, or will it “turn temper tantrums into a mental disorder” and lead to overmedication, as the chair of the previous DSM edition has warned (Frances, 2012)?

Real-world tests (*field trials*) have assessed clinician agreement when using the new DSM-5 categories (Freedman et al., 2013). Some diagnoses, such as *adult posttraumatic stress disorder* and *childhood autism spectrum disorder* fared well—with agreement near 70 percent. (If one psychiatrist or psychologist diagnosed someone with one of these disorders, there was a 70 percent chance that another mental health worker would independently give the same diagnosis.) Others, such as *antisocial personality disorder* and *generalized anxiety disorder*, fared poorly.

Critics have long faulted the DSM for casting too wide a net and bringing “almost any kind of behavior within the compass of psychiatry” (Eysenck et al., 1983). Some now worry that the DSM-5’s even wider net will extend the pathologizing of everyday life—for example, by turning childish rambunctiousness into ADHD, and bereavement grief into a depressive disorder (Frances, 2013). (See Thinking Critically About: ADHD.) Others respond that hyperactivity and depression, though needing careful definition, are genuine disorders—even when the depression was triggered by a major life stress such as a death when the grief does not go away (Kendler, 2011; Kupfer, 2012).

Other critics register a more basic complaint—that these labels are at best subjective and at worst value judgments masquerading as science. Once we label a person, we view that person differently (Bathje & Pryor, 2011; Farina, 1982; Sadler et al., 2012). Labels can change reality by putting us on alert for evidence that confirms our view. When teachers were told certain students were “gifted,” they acted in ways that elicited the behaviors they expected (Snyder, 1984). Someone who was led to think you are nasty may treat you coldly, leading you to respond as a mean-spirited person would. Labels can be self-fulfilling. They create expectations that guide how we perceive and interpret people.

The biasing power of labels was clear in a now-classic study. David Rosenhan (1973) and seven others went to hospital admissions offices, complaining (falsely) of “hearing voices” saying *empty*, *hollow*, and *thud*. Apart from this complaint and giving false names and occupations, they answered questions truthfully. All eight healthy people were misdiagnosed with disorders.

Should we be surprised? As one psychiatrist noted, if someone swallows blood, goes to an emergency room, and spits it up, should we fault the doctor for diagnosing a bleeding ulcer? Surely not. But what followed the Rosenhan study diagnoses was startling. Until being released an average of 19 days later, those eight “patients” showed no other symptoms. Yet after analyzing their (quite normal) life histories, clinicians were able to “discover” the causes of their disorders, such as having mixed emotions about a parent. Even routine note-taking behavior was misinterpreted as a symptom.

Labels matter. In another study, people watched videotaped interviews. If told the interviewees were job applicants, the viewers perceived them as normal (Langer et al., 1974, 1980).

Struggles and recovery Boston Mayor Martin Walsh spoke openly about his struggles with alcohol. His story of recovery helped him win the closest Boston mayoral election in decades.

THINKING CRITICALLY ABOUT

ADHD—Normal High Energy or Disordered Behavior?

15-4 Why is there controversy over attention-deficit/hyperactivity disorder?

Eight-year-old Todd has always been energetic. At home, he chatters away and darts from one activity to the next, rarely settling down to read a book or focus on a game. At play, he is reckless and overreacts when playmates bump into him or take one of his toys. At school, Todd fidgets, and his exasperated teacher complains that he doesn't listen, follow instructions, or stay in his seat and do his lessons. As Todd matures to adulthood, his hyperactivity likely will subside, but his inattentiveness may persist (Kessler et al., 2010).

If taken for a psychological evaluation, Todd may be diagnosed with **attention-deficit/hyperactivity disorder (ADHD)**. Some 11 percent of American 4- to 17-year-olds receive the diagnosis after displaying its key symptoms (extreme inattention, hyperactivity, and impulsivity) (Schwarz & Cohen, 2013). Studies also find 2.5 percent of adults—though the number diminishes with age—exhibit ADHD symptoms (Simon et al., 2009). The looser criteria for adult ADHD in the DSM-5 has led critics to fear increased diagnosis and overuse of prescription drugs (Frances, 2012).

To skeptics, being distractible, fidgety, and impulsive sounds like a “disorder” caused by a single genetic variation: a Y chromosome (the male sex chromosome). And sure enough, ADHD is diagnosed three times more often in boys than in girls. Children who are “a persistent pain in the neck in school” are often diagnosed with ADHD and given powerful prescription drugs (Gray, 2010). Minority youth less often receive an ADHD diagnosis than do Caucasian youth, but this difference has shrunk as minority ADHD diagnoses have increased (Getahun et al., 2013).

The problem may reside less in the child than in today's abnormal environment that forces children to do what evolution has not prepared them to do—to sit for long hours in chairs. In more natural outdoor environments, these children might seem perfectly healthy.

Rates of medication for presumed ADHD vary by age, sex, and location. Prescription drugs are more often given to teens than to younger children. Boys are nearly three times more likely to receive them than are girls. And location matters. Among 4- to 17-year-olds, prescription rates have varied from 1 percent in Nevada to 9 percent in North Carolina (CDC, 2013). Some students seek out the stimulant drugs—calling them the “good-

grade pills.” They hope to increase their focus and achievement, but the risks include the development of addiction, depressive disorders, or bipolar disorder (Schwarz, 2012).

Not everyone agrees that ADHD is being overdiagnosed. Some argue that today's more frequent diagnoses reflect increased awareness of the disorder, especially in those areas where rates are highest. They also note that diagnoses can be inconsistent—ADHD is not as clearly defined as a broken arm. Nevertheless, declared the World Federation for Mental Health (2005), “there is strong agreement among the international scientific community that ADHD is a real neurobiological disorder whose existence should no longer be debated.” A consensus statement by 75 neuroimaging researchers noted that abnormal brain activity often accompanies ADHD (Barkley et al., 2002).

What, then, is known about ADHD's causes? It is not caused by too much sugar or poor schools. There is mixed evidence suggesting that extensive TV watching and video gaming are associated with reduced cognitive self-regulation and ADHD (Bailey et al., 2011; Courage & Setliff, 2010; Ferguson et al., 2011). ADHD often coexists with a learning disorder or with defiant and temper-prone behavior. ADHD is *heritable*, and research teams are sleuthing the culprit genes and abnormal neural pathways (Lionel et al., 2014; Poelmans et al., 2011; Volkow et al., 2009; Williams et al., 2010). It is treatable with medications such as Ritalin and Adderall, which are considered stimulants but help calm hyperactivity and increase one's ability to sit and focus on a task—and to progress normally in school (Barbarese et al., 2007). Psychological therapies, such as those focused on shaping classroom and at-home behaviors, also help address the distress of ADHD (Fabiano et al., 2008).

The bottom line: Extreme inattention, hyperactivity, and impulsivity can derail social, academic, and vocational achievements, and these symptoms can be treated with medication and other therapies. But the debate continues over whether normal high energy is too often diagnosed as a psychiatric disorder, and whether there is a cost to the long-term use of stimulant drugs in treating ADHD.

attention-deficit/hyperactivity disorder (ADHD) a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity.

Other viewers who were told they were watching psychiatric or cancer patients perceived the same interviewees as “different from most people.” Therapists who thought they were watching an interview of a psychiatric patient perceived him as “frightened of his own aggressive impulses,” a “passive, dependent type,” and so forth. A label can, as Rosenhan discovered, have “a life and an influence of its own.”

Labels also have power outside the laboratory. Getting a job or finding a place to rent can be a challenge for people recently released from a mental hospital.

“My sister suffers from a bipolar disorder and my nephew from schizoaffective disorder. There has, in fact, been a lot of depression and alcoholism in my family and, traditionally, no one ever spoke about it. It just wasn’t done. The stigma is toxic.”

Actress Glenn Close, “Mental Illness: The Stigma of Silence,” 2009

Label someone as “mentally ill” and people may fear them as potentially violent (see Thinking Critically About: Are People With Psychological Disorders Dangerous?) Such negative reactions may fade as people better understand that many psychological disorders involve diseases of the brain, not failures of character (Solomon, 1996). Public figures have helped foster this new understanding by speaking openly about their own struggles with disorders such as depression and substance abuse. The more contact we have with people with disorders, the more accepting our attitudes are (Kolodziej & Johnson, 1996).

THINKING CRITICALLY ABOUT

Are People With Psychological Disorders Dangerous?

15-5 Do psychological disorders predict violent behavior?

September 16, 2013, started like any other Monday at Washington, DC’s, Navy Yard, with people arriving early to begin work. Then government contractor Aaron Alexis parked his car, entered the building, and began shooting people. An hour later, 13 people were dead, including Alexis. Reports later confirmed that Alexis had a history of mental illness. Before the shooting, he had stated that an “ultra low frequency attack is what I’ve been subject to for the last three months. And to be perfectly honest, that is what has driven me to this.” This devastating mass shooting, like the one in a Connecticut elementary school in 2012 and many others since then, reinforced public perceptions that people with psychological disorders pose a threat (Jorm et al., 2012). After the 2012 slaughter, New York’s governor declared, “People who have mental issues should not have guns” (Kaplan & Hakim, 2013).

Does scientific evidence support the governor’s statement? If disorders actually increase the risk of violence, then denying people with psychological disorders the right to bear arms might reduce violent crimes. But real life tells a different story. The vast majority of violent crimes are committed by people with no diagnosed disorder (Fazel & Grann, 2006; Walkup & Rubin, 2013).

People with disorders are more likely to be *victims* than perpetrators of violence (Marley & Bulia, 2001). According to the U.S. Surgeon General’s Office (1999, p. 7), “There is very little risk of violence or harm to a stranger from casual contact with an individual who has a mental disorder.” People with mental illness commit proportionately little gun violence. *The bottom line:* Focusing gun restrictions only on mentally ill people will likely not reduce gun violence (Friedman, 2012).

If mental illness is not a good predictor of violence, what is? Better predictors are a history of violence, use of alcohol or drugs, and access to a gun. The mass-killing shooters have one more thing in common: They tend to be young males. “We could avoid two-thirds of all crime simply by putting all able-bodied young men in cryogenic sleep from the age of 12 through 28,” said one psychologist (Lykken, 1995).

Mental disorders seldom lead to violence, and clinical prediction of violence is unreliable. What, then, are the triggers for the few people with psychological disorders who do commit violent acts? For some, the trigger is substance abuse. For others, like the Navy Yard shooter, it’s threatening delusions and hallucinated voices that command them to act (Douglas et al., 2009;

Adrees Lait/Reuters/Landov

How to prevent mass shootings? Following the Newtown, Connecticut, slaughter of 20 young children and 6 adults, people wondered: Could those at risk for violence be identified in advance by mental health workers and reported to police? Would laws that require such reporting discourage disturbed gun owners from seeking mental health treatment?

Elbogen & Johnson, 2009; Fazel et al., 2009, 2010). Whether people with mental disorders who turn violent should be held responsible for their behavior remains controversial. U.S. President Ronald Reagan’s near-assassin, John Hinckley, was sent to a hospital rather than to prison. The public was outraged. “Hinkley insane. Public mad,” declared one headline. They were outraged again in 2011, when Jared Lee Loughner killed six people and injured several others, including U.S. Representative Gabrielle Giffords. Loughner was diagnosed with schizophrenia and twice found incompetent to stand trial. He was later judged competent to stand trial, pled guilty to 19 charges of murder and attempted murder, and was sentenced to life in prison without parole.

Which decision was correct? The first two, which blamed Loughner’s “madness” for clouding his judgment? Or the final one, which decided that he should be held responsible for the acts he committed? As we come to better understand the biological and environmental bases for all human behavior, from generosity to vandalism, when should we—and should we not—hold people accountable for their actions?

Better portrayals Old stereotypes are slowly being replaced in media portrayals of psychological disorders. Recent films offer fairly realistic depictions. *Iron Man 3* (2013) portrayed a main character, shown here, with post-traumatic stress disorder. *Black Swan* (2010) dramatized a lead character suffering a delusional disorder. *A Single Man* (2009) depicted depression.

Despite their risks, diagnostic labels have benefits. Mental health professionals use labels to communicate about their cases, to comprehend the underlying causes, and to discern effective treatment programs. Researchers use labels when discussing work that explores the causes and treatments of disorders. Clients are often relieved to learn that the nature of their suffering has a name, and that they are not alone in experiencing this collection of symptoms.

RETRIEVAL PRACTICE

• What is the value, and what are the dangers, of labeling individuals with disorders?

ANSWER: Therapists and others use disorder labels to communicate with one another using a common language, and to share concepts during research. Clients may benefit from knowing that they are not the only ones with these symptoms. The dangers of labeling people are that (1) people may begin to act as they have been labeled, and (2) the labels can trigger assumptions that will change our behavior toward those we label.

Rates of Psychological Disorders

15-6 How many people have, or have had, a psychological disorder? Is poverty a risk factor?

Who is most vulnerable to psychological disorders? At what times of life? To answer such questions, various countries have conducted lengthy structured interviews with representative samples of thousands of their citizens. After asking hundreds of questions that probed for symptoms—“Has there ever been a period of two weeks or more when you felt like you wanted to die?”—the researchers have estimated the current, prior-year, and lifetime prevalence of various disorders.

How many people have, or have had, a psychological disorder? More than most of us suppose:

- The U.S. National Institute of Mental Health (2008, based on Kessler et al., 2005) has estimated that just over 1 in 4 adult Americans “suffer from a diagnosable mental disorder in a given year” (TABLE 15.2).
- A large-scale World Health Organization (2004a) study—based on 90-minute interviews of 60,463 people—estimated the number of prior-year mental disorders in 20 countries. As FIGURE 15.2 on the next page displays, the lowest rate of reported mental disorders was in Shanghai, the highest rate in the United States. Moreover, immigrants to the United States from Mexico, Africa, and Asia averaged better mental health than their U.S. counterparts with the same ethnic heritage (Breslau

“What’s the use of their having names,” the Gnat said, “if they won’t answer to them?”

“No use to *them*,” said Alice; “but it’s useful to the people that name them, I suppose.”

Lewis Carroll, *Through the Looking-Glass*, 1871

▼ TABLE 15.2
Percentage of Americans Reporting Selected Psychological Disorders in the Past Year

Psychological Disorder	Percentage
Generalized anxiety disorder	3.1
Social anxiety disorder	6.8
Phobia of specific object or situation	8.7
Depressive disorders or bipolar disorder	9.5
Obsessive-compulsive disorder (OCD)	1.0
Schizophrenia	1.1
Posttraumatic stress disorder (PTSD)	3.5
Attention-deficit/hyperactivity disorder (ADHD)	4.1

Data from: National Institute of Mental Health, 2008.

▼ **FIGURE 15.2**
Prior-year prevalence of disorders in selected areas From World Health Organization (WHO, 2004a) interviews in 20 countries.

et al., 2007; Maldonado-Molina et al., 2011). For example, compared with people who have recently immigrated from Mexico, Mexican-Americans born in the United States are at greater risk of mental disorder—a phenomenon known as the *immigrant paradox* (Schwartz et al., 2010).

What increases vulnerability to mental disorders? As TABLE 15.3 indicates, there is a wide range of risk and protective factors for mental disorders. But one predictor of mental disorder, poverty, crosses ethnic and gender lines. The incidence of serious psychological disorders has been doubly high among those below the poverty line (CDC, 1992). Like so many other correlations, the poverty-disorder association raises further questions: Does poverty cause disorders? Or do disorders cause poverty? It is both, though the answer varies with the disorder. Schizophrenia understandably leads to poverty. Yet the stresses and demoralization of poverty can also precipitate disorders, especially depression in women and substance abuse in men (Dohrenwend et al., 1992).

▼ **TABLE 15.3**
Risk and Protective Factors for Mental Disorders

Risk Factors	Protective Factors
Academic failure	Aerobic exercise
Birth complications	Community offering empowerment, opportunity, and security
Caring for those who are chronically ill or who have a neurocognitive disorder	Economic independence
Child abuse and neglect	Effective parenting
Chronic insomnia	Feelings of mastery and control
Chronic pain	Feelings of security
Family disorganization or conflict	Literacy
Low birth weight	Positive attachment and early bonding
Low socioeconomic status	Positive parent-child relationships
Medical illness	Problem-solving skills
Neurochemical imbalance	Resilient coping with stress and adversity
Parental mental illness	Self-esteem
Parental substance abuse	Social and work skills
Personal loss and bereavement	Social support from family and friends
Poor work skills and habits	
Reading disabilities	
Sensory disabilities	
Social incompetence	
Stressful life events	
Substance abuse	
Trauma experiences	

Research from: World Health Organization (WHO, 2004b,c).

In one natural experiment on the poverty-pathology link, researchers tracked rates of behavior problems in North Carolina Native American children as economic development enabled a dramatic reduction in their community’s poverty rate. As the study began, children of poverty exhibited more deviant and aggressive behaviors. After four years, children whose families had moved above the poverty line exhibited a 40 percent decrease in the behavior problems. Those who continued in their previous positions below or above the poverty line exhibited no change (Costello et al., 2003).

At what times of life do disorders strike? Usually by early adulthood. “Over 75 percent of our sample with any disorder had experienced [their] first symptoms by age 24,”

reported Lee Robins and Darrel Regier (1991, p. 331). Among the earliest to appear are the symptoms of antisocial personality disorder (median age 8) and of phobias (median age 10). Alcohol use disorder, obsessive-compulsive disorder, bipolar disorder, and schizophrenia symptoms appear at a median age near 20. Major depressive disorder often hits somewhat later, at a median age of 25.

RETRIEVAL PRACTICE

- What is the relationship between poverty and psychological disorders?

ANSWER: Poverty-related stresses can help trigger disorders, but disabling disorders can also contribute to poverty. Thus, poverty and disorder are often a chicken-and-egg situation, and it's hard to know which came first.

REVIEW Introduction to Psychological Disorders

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

15-1 How should we draw the line between normality and disorder?

15-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

15-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

15-4 Why is there controversy over attention-deficit/hyperactivity disorder?

Anxiety Disorders, OCD, and PTSD

Anxiety is part of life. Speaking in front of a class, peering down from a ladder, or waiting to play in a big game, any one of us might feel anxious. Anxiety may even cause us to avoid talking or making eye contact—"shyness," we call it. Fortunately for most of us, our uneasiness is not intense and persistent. Some of us, however, are more prone to notice and remember threats (Mitte, 2008). When the brain's danger-detection system becomes hyperactive, we are at greater risk for an *anxiety disorder*, or for two other disorders that involve anxiety: *obsessive-compulsive disorder (OCD)* or *posttraumatic stress disorder (PTSD)*.¹

1. OCD and PTSD were formerly classified as anxiety disorders, but the DSM-5 now classifies them separately.

Anxiety Disorders

15-7 How do generalized anxiety disorder, panic disorder, and phobias differ?

The **anxiety disorders** are marked by distressing, persistent anxiety or dysfunctional anxiety-reducing behaviors. Let's take a closer look at three of them:

- *Generalized anxiety disorder*, in which a person is unexplainably and continually tense and uneasy
- *Panic disorder*, in which a person experiences *panic attacks*—sudden episodes of intense dread—and fears the unpredictable onset of the next episode
- *Phobias*, in which a person is intensely and irrationally afraid of a specific object, activity, or situation

Generalized Anxiety Disorder

For the past two years, Tom, a 27-year-old electrician, has been bothered by dizziness, sweating palms, heart palpitations, and ringing in his ears. He feels on edge and sometimes finds himself shaking. With reasonable success, he hides his symptoms from his family and co-workers. But he allows himself few other social contacts, and occasionally he has to leave work. His family doctor and a neurologist can find no physical problem.

Tom's unfocused, out-of-control, agitated feelings suggest a **generalized anxiety disorder**, which is marked by excessive and uncontrollable worry. The symptoms of this disorder are commonplace; their persistence, for six months or more, is not. People with this condition worry continually, and they are often jittery, agitated, and sleep-deprived. Concentration is difficult as attention switches from worry to worry. Their tension and apprehension may leak out through furrowed brows, twitching eyelids, trembling, perspiration, or fidgeting from autonomic nervous system arousal.

The person may not be able to identify, and therefore relieve or avoid, the tension's cause. To use Sigmund Freud's term, the anxiety is *free-floating* (not linked to a specific stressor or threat). Generalized anxiety disorder is often accompanied by depressed mood, but even without depression it tends to be disabling (Hunt et al., 2004; Moffitt et al., 2007b). Moreover, it may lead to physical problems, such as high blood pressure.

Women are twice as likely as men to experience generalized anxiety disorder (McLean & Anderson, 2009). This anxiety gender difference was reflected in a Gallup poll taken eight months after 9/11, when more U.S. women (34 percent) than men (19 percent) said they were still less willing than before 9/11 to go into skyscrapers or fly on planes. And in early 2003, more women (57 percent) than men (36 percent) said they were "somewhat worried" about becoming a terrorist victim (Jones, 2003).

Some people with generalized anxiety disorder were maltreated and inhibited as children (Moffitt et al., 2007a). As time passes, however, emotions tend to mellow, and by age 50, generalized anxiety disorder becomes fairly rare (Rubio & López-Ibor, 2007).

Panic Disorder

For the 1 person in 75 with **panic disorder**, anxiety suddenly escalates into a terrifying panic attack—a minutes-long episode of intense fear that something horrible is about to happen. Physical symptoms, such as irregular heartbeat, chest pains, shortness of breath, choking, trembling, or dizziness may accompany the panic. One woman recalled suddenly feeling

hot and as though I couldn't breathe. My heart was racing and I started to sweat and tremble and I was sure I was going to faint. Then my fingers started to feel numb and tingly and things seemed unreal. It was so bad I wondered if I was dying and asked my husband to take me to the emergency room. By the time we got there (about 10 minutes) the worst of the attack was over and I just felt washed out (Greist et al., 1986).

anxiety disorders psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety.

generalized anxiety disorder an anxiety disorder in which a person is continually tense, apprehensive, and in a state of autonomic nervous system arousal.

panic disorder an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person experiences terror and accompanying chest pain, choking, or other frightening sensations. Often followed by worry over a possible next attack.

phobia an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation.

Sam Greenwood/Getty Images

Sam Greenwood/Getty Images

These anxiety tornados strike suddenly, wreak havoc, and disappear, but they are not forgotten. Ironically, worries about anxiety—perhaps fearing another panic attack, or fearing anxiety-caused sweating in public—can amplify anxiety symptoms (Olatunji & Wolitzky-Taylor, 2009). After several panic attacks, people may avoid situations where the previous panic attacks have struck. If their fear is intense enough, people may develop *agoraphobia*, fear or avoidance of situations in which escape might be difficult when panic strikes. Given such fear, people may avoid being outside the home, in a crowd, on a bus, or in an elevator.

Charles Darwin began suffering panic disorder at age 28, after spending five years sailing the world. Because of the attacks, he moved to the country, avoided social gatherings, and traveled only in his wife's company. But the relative seclusion did free him to focus on developing his evolutionary theory. “Even ill health,” he reflected, “has saved me from the distraction of society and its amusements” (quoted in Ma, 1997).

Smokers have at least a doubled risk of panic disorder (Zvolensky & Bernstein, 2005). They also show greater panic symptoms in situations that often produce panic attacks, such as when they hyperventilate (Knuts et al., 2010). Because nicotine is a stimulant, lighting up doesn't lighten up.

Phobias

We all live with some fears. But people with **phobias** are consumed by a persistent, irrational fear and avoidance of some object, activity, or situation. *Specific phobias* may focus on animals, insects, heights, blood, or close spaces (**FIGURE 15.3** on the next page). Many people avoid the triggers, such as high places, that arouse their fear, and they manage to live with their phobia. Others are incapacitated by their efforts to avoid the feared situation. Marilyn, an otherwise healthy and happy 28-year-old, fears thunderstorms so intensely that she feels anxious as soon as a weather forecaster mentions possible storms later in the week. If her husband is away and a storm is forecast, she may stay with a close relative. During a storm, she hides from windows and buries her head to avoid seeing the lightning.

Not all phobias have specific triggers. *Social anxiety disorder* (formerly called “social phobia”) is shyness taken to an extreme. People with this disorder have an intense fear of other people's negative judgments. They may avoid potentially embarrassing social situations—such as speaking up, eating out, or going to parties—or they may sweat or tremble when doing so.

Panicked playing Golfer Charlie Beljan experienced what he later learned were panic attacks during an important tournament. His thumping heartbeat and shortness of breath led him to think he was having a heart attack. But hospital tests revealed that his symptoms, though serious, were not related to a physical illness. He recovered, went on to win \$846,000, and has become an inspiration to others.

▼ **FIGURE 15.3**
Some common and uncommon specific fears Researchers surveyed Dutch people to identify the most common events or objects they feared. A strong fear becomes a phobia if it provokes a compelling but irrational desire to avoid the dreaded object or situation. (Data from Depla et al., 2008.)

Martin Harvey/Digital Vision/Getty Images

RETRIEVAL PRACTICE

- Unfocused tension, apprehension, and arousal are symptoms of _____ disorder.
- Those who experience unpredictable periods of terror and intense dread, accompanied by frightening physical sensations, may be diagnosed with a _____ disorder.
- If a person is focusing anxiety on specific feared objects or situations, that person may have a _____.

ANSWER: generalized anxiety

ANSWER: panic

ANSWER: phobia

Obsessive-Compulsive Disorder (OCD)

The New Yorker Collection, 2010. Joe Dator, from cartoonbank.com. All Rights Reserved

“Spin your partner round and round, then spin your partner round again, spin her round six more times, now touch the light switch near the door.”

15-8 What is OCD?

As with the anxiety disorders, we can see aspects of **obsessive-compulsive disorder (OCD)** in our everyday behavior. We all may at times be obsessed with senseless or offensive thoughts that will not go away. Or we may engage in compulsive behaviors, perhaps lining up books and pencils “just so” before studying. Obsessive thoughts and compulsive behaviors cross the fine line between normality and disorder when they *persistently interfere* with everyday living and cause distress. Checking to see you locked the door is normal; checking 10 times is not. Washing your hands is normal; washing so often that your skin becomes raw is not. (TABLE 15.4 offers more examples.) At some time during their lives, often during their late teens or twenties, 1 to nearly 3 percent of

▼ **TABLE 15.4**
Common Obsessions and Compulsions Among Children and Adolescents With Obsessive-Compulsive Disorder

Thought or Behavior	Percentage Reporting Symptom
Obsessions (repetitive <i>thoughts</i>)	
Concern with dirt, germs, or toxins	40
Something terrible happening (fire, death, illness)	24
Symmetry, order, or exactness	17
Compulsions (repetitive <i>behaviors</i>)	
Excessive hand washing, bathing, toothbrushing, or grooming	85
Repeating rituals (in/out of a door, up/down from a chair)	51
Checking doors, locks, appliances, car brakes, homework	46

Source: Data from Rapoport, 1989.

obsessive-compulsive disorder (OCD) a disorder characterized by unwanted repetitive thoughts (obsessions), actions (compulsions), or both.

posttraumatic stress disorder (PTSD) a disorder characterized by haunting memories, nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience.

people cross that line from normal preoccupations and fussiness to debilitating disorder (Kessler et al., 2012). An analysis of 14 twin studies showed that OCD has a strong genetic basis (Taylor, 2011). Although the person knows them to be irrational, the anxiety-fueled obsessive thoughts become so haunting, the compulsive rituals so senselessly time-consuming, that effective functioning becomes impossible.

 **LaunchPad** For a 7-minute video illustrating struggles associated with compulsive rituals, visit LaunchPad's *Obsessive-Compulsive Disorder: A Young Mother's Struggle*.

Former professional basketball player Royce White, who is open about his obsessive-compulsive disorder, said that his wealth allowed him to purchase a large house. What was the most difficult part of his transition to mansion living? “The toughest thing is going around and seeing that dust has collected in a room [I] don’t use often. And then I’ve got to spend 30 minutes dusting that thing” (Wrenn, 2012).

OCD is more common among teens and young adults than among older people (Samuels & Nestadt, 1997). A 40-year follow-up study of 144 Swedish people diagnosed with the disorder found that, for most, the obsessions and compulsions had gradually lessened, though only 1 in 5 had completely recovered (Skoog & Skoog, 1999).

Posttraumatic Stress Disorder (PTSD)

15-9 What is PTSD?

As an Iraq war soldier, Jesse “saw the murder of children and women. It was just horrible for anyone to experience.” After calling in a helicopter strike on one house where he had seen ammunition crates carried in, he heard the screams of children from within. “I didn’t know there were kids there,” he recalled. Back home in Texas, he suffered “real bad flashbacks” (Welch, 2005).

Jesse is not alone. In one study of 103,788 veterans returning from Iraq and Afghanistan, 25 percent were diagnosed with a psychological disorder (Seal et al., 2007). Some had *traumatic brain injuries (TBI)*, but the most frequent diagnosis was **posttraumatic stress disorder (PTSD)**. Typical symptoms include recurring haunting memories and nightmares, a numb feeling of social withdrawal, jumpy anxiety, and trouble sleeping (Germain, 2013; Hoge et al., 2004, 2006, 2007; Kessler, 2000). Although many battle-scarred veterans have been diagnosed with PTSD, others also suffer from this disorder. Survivors of accidents, disasters, and violent and sexual assaults (including an estimated two-thirds of prostitutes) have experienced PTSD symptoms (Brewin et al., 1999; Farley et al., 1998; Taylor et al., 1998).

The greater one’s emotional distress during a trauma, the higher the risk for post-traumatic symptoms (Ozer et al., 2003). Among American military personnel in Afghanistan, 7.6 percent of combatants and 1.4 percent of noncombatants developed PTSD (McNally, 2012). Among New Yorkers who witnessed or responded to the 9/11 terrorist attacks, most did not experience PTSD (Neria et al., 2011). After experiencing a traumatic life event, about 5 to 10 percent of people develop PTSD (Bonanno et al., 2011). PTSD diagnoses among survivors who had been inside the World Trade Center during the attack were, however, double the rates found among those who were outside (Bonanno et al., 2006).

About half of us will experience at least one traumatic event in our lifetime. Why do some people develop PTSD after a traumatic event, but others don’t? Some people may have more sensitive emotion-processing limbic systems that flood their bodies with stress hormones (Kosslyn, 2005; Ozer & Weiss, 2004). PTSD patients have smaller amygdala—that acorn-shaped brain region that governs fear (Morey et al., 2012). Genes and gender also matter. Twins, compared with nontwins, more commonly share PTSD

Making everything perfect

Soccer star David Beckham has openly discussed his obsessive-compulsive tendencies, which have driven him to line up objects in pairs or to spend hours straightening furniture (Adams, 2011).

Bringing the war home Nearly a quarter-million Iraq and Afghanistan war veterans have been diagnosed with PTSD or traumatic brain injury (TBI). Many vets participate in an intensive recovery program using deep breathing, massage, and group and individual discussion techniques to treat their PTSD or TBI.

© Lynn Johnson/National Geographic Society/Corbis

cognitive risk factors (Gilbertson et al., 2006). And the odds of getting this disorder after a traumatic event are about two times higher for women than for men (Olff et al., 2007; Ozer & Weiss, 2004).

Some psychologists believe that PTSD has been overdiagnosed, due partly to a broadening definition of *trauma* (Dobbs, 2009; McNally, 2003). Too often, say some critics, PTSD gets stretched to include normal bad memories and dreams after a bad experience. In such cases, well-intentioned attempts to have people relive the trauma may amplify their emotions and pathologize normal stress reactions (Wakefield & Spitzer, 2002). For example, survivors may be “debriefed” right after a trauma and asked to revisit the experience and vent emotions. This tactic has been generally ineffective and sometimes harmful (Bonanno et al., 2010).

Most people, male and female, display an impressive *survivor resiliency*, or ability to recover after severe stress (Bonanno et al., 2010). For more on human resilience and on the *posttraumatic growth* that some experience, see Chapter 16.

RETRIEVAL PRACTICE

- Those who express anxiety through unwanted repetitive thoughts or actions may have a(n) _____-_____ disorder.
- Those with symptoms of recurring memories and nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia for weeks after a traumatic event may be diagnosed with _____ disorder.

ANSWER: obsessive-compulsive

ANSWER: posttraumatic stress

Understanding Anxiety Disorders, OCD, and PTSD

15-10 How do conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD?

Anxiety is both a feeling and a cognition—a doubt-laden appraisal of one’s safety or social skill. How do these anxious feelings and cognitions arise? Sigmund Freud’s psychoanalytic theory proposed that, beginning in childhood, people *repress* intolerable impulses, ideas, and feelings. This submerged mental energy sometimes, he thought, leaks out in odd symptoms, such as anxious handwashing. Few of today’s psychologists share Freud’s interpretation of anxiety. Most believe that three modern perspectives—conditioning, cognition, and biology—are more helpful.

Conditioning

Some bad events come with a warning. Your underdog team might lose the big game. You aren’t prepared and you may fail your quiz. You’re running late and might miss the bus. But when bad events happen unpredictably and uncontrollably, anxiety and other disorders often develop (Field, 2006; Mineka & Oehlberg, 2008). In a classic experiment, an infant called “Little Albert” learned to fear furry objects that were paired with loud noises. In other experiments, researchers have created anxious animals by giving rats unpredictable electric shocks (Schwartz, 1984). The rats, like assault victims who report feeling anxious when returning to the scene of the crime, became uneasy in their lab environment. The lab had become a cue for fear.

Such research helps explain why anxious people are hyperattentive to possible threats, and how panic-prone people come to associate anxiety with certain cues (Bar-Haim et al., 2007; Bouton et al., 2001). In one survey, 58 percent of those with social anxiety disorder experienced their disorder after a traumatic event (Ost & Hugdahl, 1981).

Through conditioning, the short list of naturally painful and frightening events can multiply into a long list of human fears. Can you recall a frightening event that left you fearful for a while? We can. I [DM] was headed home when my car was struck by another when its driver missed a stop sign. For months afterward, I felt a twinge of unease as a car approached from a side street. Likewise, I [ND] remember watching a terrifying movie about spiders, *Arachnophobia*, when a severe thunderstorm struck and the theater lost power. For months, I experienced anxiety at the sight of spiders or harmless cobwebs.

How might conditioning magnify a single painful and frightening event into a full-blown phobia? The answer lies in part in two conditioning processes: *stimulus generalization* and *reinforcement*.

Stimulus generalization occurs when a person experiences a fearful event and later develops a fear of similar events. Each of us [DM and ND] generalized our fears: One of us feared cars approaching from side streets and the other feared spiders. Those fears eventually disappeared, but sometimes fears can linger and grow. Marilyn's thunderstorm phobia may have similarly generalized after a terrifying or painful experience during a thunderstorm.

Once fears and anxieties arise, *reinforcement* helps maintain them. Anything that helps us avoid or escape the feared situation can be reinforcing because it reduces anxiety and gives us a feeling of relief. Fearing a panic attack, we may decide not to leave the house. Reinforced by feeling calmer, we are likely to repeat that maladaptive behavior in the future (Antony et al., 1992). So, too, with compulsive behaviors. If washing our hands relieves our feelings of anxiety, we may wash our hands again when those feelings return.

Cognition

Conditioning influences our feelings of anxiety, but so does cognition—our thoughts, memories, interpretations, and expectations. By observing others, we can learn to fear what they fear. Nearly all monkeys raised in the wild fear snakes, yet lab-raised monkeys do not. Surely, most wild monkeys do not actually suffer snake bites. Do they learn their fear through observation? To find out, Susan Mineka (1985, 2002) experimented with six monkeys raised in the wild (all strongly fearful of snakes) and their lab-raised offspring (virtually none of which feared snakes). After repeatedly observing their parents or peers refusing to reach for food in the presence of a snake, the younger monkeys developed a similar strong fear of snakes. When the monkeys were retested three months later, their learned fear persisted. We humans learn many of our own fears by observing others (Helsen et al., 2011; Olsson et al., 2007).

Our past experiences shape our expectations and influence our interpretations and reactions. Whether we interpret the creaky sound in the old house simply as the wind or as a possible knife-wielding intruder determines whether we panic. People with anxiety disorders tend to be *hypervigilant*. A pounding heart signals a heart attack. A lone spider near the bed becomes a likely infestation. An everyday disagreement with a friend or boss spells possible doom for the relationship. Anxiety is especially common when people cannot switch off such intrusive thoughts and perceive a loss of control and a sense of helplessness (Franklin & Foa, 2011).

Biology

There is, however, more to anxiety disorders, OCD, and PTSD than conditioning and cognitive processes alone. Why will some of us develop lasting phobias or PTSD after suffering traumas? Why do we all learn some fears so readily? Why are some of us more vulnerable? The biological perspective offers insight.

Hemera Technologies/PhotoObjects.net/360/Getty Images

Genes Genes matter. Pair a traumatic event with a sensitive, high-strung temperament and the result may be a new phobia (Belsky & Pluess, 2009). Some of us have genes that make us like orchids—fragile, yet capable of beauty under favorable circumstances. Others of us are like dandelions—hardy, and able to thrive in varied circumstances (Ellis & Boyce, 2008; Pluess & Belsky, 2013).

Among monkeys, fearfulness runs in families. A monkey reacts more strongly to stress if its close biological relatives are anxiously reactive (Suomi, 1986). So, too, with people. If one identical twin has an anxiety disorder, the other is likewise at risk (Hettema et al., 2001; Kendler et al., 2002a,b; Van Houtem et al., 2013). Even when raised separately, identical twins may develop similar phobias (Carey, 1990; Eckert et al., 1981). One pair of 35-year-old female identical twins independently became so afraid of water that each would wade in the ocean backward and only up to the knees.

Given the genetic contribution to anxiety disorders, researchers are now sleuthing the culprit genes. One research team identified 17 gene variations associated with typical anxiety disorder symptoms (Hovatta et al., 2005). Other teams have found genes associated specifically with OCD (Taylor, 2013).

Genes can influence disorders by regulating neurotransmitters. Some studies point to an “anxiety gene” that affects brain levels of *serotonin*, a neurotransmitter that influences sleep, mood, and attention to negative images (Canli, 2008; Pergamin-Hight et al., 2012). Other studies implicate genes that regulate the neurotransmitter *glutamate* (Lafleur et al., 2006; Welch et al., 2007). With too much glutamate, the brain’s alarm centers become overactive.

Among PTSD patients, a history of child abuse leaves long-term *epigenetic* marks, increasing the likelihood that a genetic vulnerability to the disorder will be expressed (Mehta et al., 2013). Suicide victims show a similar epigenetic effect (McGowan et al., 2009).

The Brain Our experiences change our brain, paving new pathways. Traumatic fear-learning experiences can leave tracks in the brain, creating fear circuits within the amygdala (Etkin & Wager, 2007; Kolassa & Elbert, 2007; Heringa et al., 2013). These fear pathways create easy inroads for more fear experiences (Armony et al., 1998).

Anxiety-related disorders differ from one another, but they all involve biological events. In OCD, for example, when the disordered brain detects that something is amiss, it generates a mental hiccup of repeating thoughts (obsessions) or actions (compulsions) (Gehring et al., 2000). Brain scans of people with PTSD show higher-than-normal activity in the amygdala when they view traumatic images (Nutt & Malizia, 2004). Brain scans of people with OCD reveal elevated activity in specific brain areas during behaviors such as compulsive hand washing, checking, ordering, or hoarding (Insel, 2010; Mataix-Cols et al., 2004, 2005). These brain areas are not only more active among people with OCD, they are also enlarged (Rotge et al., 2010). As **FIGURE 15.4** shows, the *anterior cingulate cortex*, a brain region that monitors our actions and checks for errors, seems especially likely to be hyperactive (Maltby et al., 2005). When deciding to get rid of one’s personal possessions, those with hoarding disorder also show elevated activity in the anterior cingulate cortex (Tolin et al., 2012).

Some antidepressant drugs dampen this fear-circuit activity and its associated obsessive-compulsive behavior. Fears can also be blunted by giving people drugs as they recall and then rerecord (“reconsolidate”) a traumatic experience (Kindt et al., 2009; Norberg, et al., 2008). Although they don’t forget the experience, the associated emotion is largely erased.

Natural Selection We seem biologically prepared to fear threats faced by our ancestors. Our phobias focus on such specific fears: spiders, snakes, and other animals; enclosed spaces and heights; storms and darkness. (Those fearless about these occasional threats were less likely to survive and leave descendants.) Thus, even in Britain, with only one poisonous snake species, people often fear snakes. It is easy to

▼ FIGURE 15.4

An obsessive-compulsive brain

Neuroscientists Nicholas Maltby, David Tolin, and their colleagues (2005) used functional MRI scans to compare the brains of those with and without OCD as they engaged in a challenging cognitive task. The scans of those with OCD showed elevated activity in the anterior cingulate cortex in the brain’s frontal area (indicated by the yellow area on the far right).

Fearless The biological perspective helps us understand why most of us have more fear of heights than does Felix Baumgartner, shown here skydiving from 24 miles above the Earth in 2012.

condition and hard to extinguish fears of such “evolutionarily relevant” stimuli (Coelho & Purkis, 2009; Davey, 1995; Öhman, 2009). Some of our modern fears can also have an evolutionary explanation. A fear of flying may be rooted in our biological predisposition to fear confinement and heights.

Compare our easily conditional fears to what we *do not* easily learn to fear. World War II air raids, for example, produced remarkably few lasting phobias. As the air blitzes continued, the British, Japanese, and German populations did not become more and more panicked. Rather, they grew more indifferent to planes outside their immediate neighborhoods (Mineka & Zinbarg, 1996). Evolution has not prepared us to fear bombs dropping from the sky.

Just as our phobias focus on dangers faced by our ancestors, our compulsive acts typically exaggerate behaviors that contributed to our species’ survival. Grooming gone wild becomes hair pulling. Washing up becomes ritual hand washing. Checking territorial boundaries becomes rechecking an already locked door (Rapoport, 1989).

RETRIEVAL PRACTICE

- Researchers believe that conditioning and cognitive processes contribute to anxiety disorders, OCD, and PTSD. What *biological* factors also contribute to these disorders?
- ANSWER: Biological factors include inherited temperament differences and other gene variations; learned fears that have altered brain pathways; and outdated, inherited responses that had survival value for our distant ancestors.

REVIEW Anxiety Disorders, OCD, and PTSD

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

Depressive Disorders and Bipolar Disorder

15-11 How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

“My life had come to a sudden stop. I was able to breathe, to eat, to drink, to sleep. I could not, indeed, help doing so; but there was no real life in me.”

Leo Tolstoy, *My Confession*, 1887

“If someone offered you a pill that would make you permanently happy, you would be well advised to run fast and run far. Emotion is a compass that tells us what to do, and a compass that is perpetually stuck on NORTH is worthless.”

Daniel Gilbert,
“The Science of Happiness,” 2006

Most of us will have some direct or indirect experience with depression. If you are like many college students, at some time during this year—more likely the dark months of winter than the bright days of summer—you may experience some of depression’s symptoms. You might feel deeply discouraged about the future, dissatisfied with your life, or socially isolated. You may lack the energy to get things done or even to force yourself out of bed; be unable to concentrate, eat, or sleep normally; or even wonder if you would be better off dead. Perhaps academic success came easily to you before, but now you find that disappointing grades jeopardize your goals. Maybe social stress, such as loneliness, feeling you are the target of prejudice, or experiencing a romantic breakup, have plunged you into despair. And perhaps low self-esteem increases your brooding, worsening your self-torment (Sowislo & Orth, 2012). Likely you think you are more alone in having such negative feelings than you really are (Jordan et al., 2011). In one national survey of American collegians, 31 percent said they had at some time in the past year, “felt so depressed that it was difficult to function” (ACHA, 2009). Misery has more company than most suppose.

Brad Wenner/Moment Select/Getty Images

Joy, contentment, sadness, and despair exist at different points on a continuum, points at which any of us may find ourselves at any given moment. To feel bad in reaction to profoundly sad events is to be in touch with reality. In such times, there is an up side to being down. Sadness is like a car’s low-fuel light—a signal that warns us to stop and take appropriate measures. Biologically speaking, life’s purpose is not happiness but survival and reproduction. Coughing, vomiting, swelling, and pain protect the body from dangerous toxins. Similarly, depression resembles a sort of psychic hibernation: It slows us down, defuses aggression, helps us let go of unattainable goals, and restrains risk taking (Andrews & Thomson, 2009a,b; Wrosch & Miller, 2009). When we grind temporarily to a halt and reassess our life, as depressed people do, we can redirect our energy in more promising ways (Watkins, 2008). We may also make better decisions. Even mild sadness can improve people’s recall, make them more discerning, and help them make complex decisions (Forgas, 2009). It can also help them process and recall faces more accurately (Hills et al., 2011). There is sense to suffering.

But sometimes this response, taken to an extreme, can become seriously maladaptive and signal a disorder. The difference between a blue mood after bad news and a depression-related disorder is like the difference between gasping for breath after a hard run and being chronically short of breath.

In this section, we consider three disorders in which depression impairs daily living:

- *Major depressive disorder*, a persistent state of hopelessness and lethargy
- *Persistent depressive disorder*, in which a person experiences milder depressive feelings
- *Bipolar disorder* (formerly called *manic-depressive disorder*), in which a person alternates between depression and overexcited hyperactivity

Major Depressive Disorder

Major depressive disorder occurs when at least five signs of depression last two or more weeks (TABLE 15.5). The symptoms must cause near-daily distress or impairment and not be attributable to substance use or another medical or mental illness.

To sense what major depression feels like, suggest some clinicians, imagine combining the anguish of grief with the sluggishness of bad jet lag. If stress-related anxiety is a “crackling, menacing brushfire,” noted biologist Robert Sapolsky (2003), “depression is a suffocating heavy blanket thrown on top of it.”

▼ **TABLE 15.5**
Diagnosing Major Depressive Disorder

The DSM-5 classifies major depressive disorder as the presence of at least five of the following symptoms over a two-week period of time (minimally including depressed mood or reduced interest (American Psychiatric Association, 2013).

• Depressed mood most of the time
• Dramatically reduced interest or enjoyment in most activities most of the time
• Significant challenges regulating appetite and weight
• Significant challenges regulating sleep
• Physical agitation or lethargy
• Feeling listless or with much less energy
• Feeling worthless; or feeling unwarranted guilt
• Problems in thinking, concentrating, or making decisions
• Thinking repetitively of death and suicide

Adults diagnosed with persistent depressive disorder (also called *dysthymia*) experience a mildly depressed mood more often than not for two years or more (American Psychiatric Association, 2013). They also display at least two of the following symptoms:

- Difficulty with decision-making and concentration
- Feeling hopeless
- Poor self-esteem
- Reduced energy levels
- Problems regulating sleep
- Problems regulating appetite

Bipolar Disorder

With or without therapy, episodes of major depression usually end, and people temporarily or permanently return to their previous behavior patterns. However, some people rebound to, or sometimes start with, the opposite emotional extreme—the hyperactive, overly talkative, wildly optimistic state of **mania**. If depression is living in slow motion, mania is fast forward. Alternating between depression and mania signals **bipolar disorder**.

Adolescent mood swings, from rage to bubbly, can, when prolonged, lead to a bipolar diagnosis. Between 1994 and 2003, diagnoses of bipolar disorder swelled. U.S. National Center for Health Statistics annual physician surveys revealed an astonishing 40-fold increase in bipolar disorder diagnoses in those 19 and under—from an estimated 20,000 to 800,000 (Carey, 2007; Flora & Bobby, 2008; Moreno et al., 2007). Americans are twice as likely as people of other countries to have ever had a diagnosis of bipolar disorder

major depressive disorder a disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure.

mania a hyperactive, wildly optimistic state in which dangerously poor judgment is common.

bipolar disorder a disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.)

Bipolar disorder Artist Abigail Southworth illustrated her experience of bipolar disorder.

▼ **TABLE 15.6**
Percentage Answering Yes
When Asked “Have You Cried
Today?”

	Percentage who cried	
	Men	Women
August	4%	7%
December	8%	21%

Source: Time/CNN survey, 1994

(Merikangas et al., 2011). The new popularity of the diagnosis, given in two-thirds of the cases to boys, has profited companies whose drugs are prescribed to lessen mood swings. Under the new DSM-5 classifications, the number of child and adolescent bipolar diagnoses will likely decline, because some individuals with emotional volatility will be diagnosed with *disruptive mood dysregulation disorder* (Miller, 2010).

During the manic phase, people with bipolar disorder typically have little need for sleep. They show fewer sexual inhibitions. Their positive emotions persist abnormally (Gruber, 2011; Gruber et al., 2013). Their speech is loud, flighty, and hard to interrupt. They find advice irritating. Yet they need protection from their own poor judgment, which may lead to reckless spending or unsafe sex. Thinking fast feels good, but it also increases risk taking (Chandler & Pronin, 2012; Pronin, 2013).

For some people suffering depressive disorders or bipolar disorder, symptoms may have a *seasonal pattern*. Depression may regularly return each fall or winter, and mania (or a reprieve from depression) may dependably arrive with spring. For many others, winter darkness simply means more blue moods. When asked “Have you cried today?” Americans have agreed more often in the winter (TABLE 15.6).

In milder forms, mania’s energy and flood of ideas fuel creativity. George Frideric Handel, who may have suffered from a mild form of bipolar disorder, composed his nearly four-hour-long *Messiah* (1742) during three weeks of intense, creative energy (Keynes, 1980). Robert Schumann composed 51 musical works during two years of mania (1840 and 1849) but none during 1844, when he was severely depressed (Slater & Meyer, 1959). Those who rely on precision and logic, such as architects, designers, and journalists, suffer bipolar disorder less often than do those who rely on emotional expression and vivid imagery (Ludwig, 1995). Composers, artists, poets, novelists, and entertainers seem especially prone (Jamison, 1993, 1995; Kaufman & Baer, 2002; Ludwig, 1995). Indeed, one analysis of over a million individuals showed that the only psychiatric condition linked to working in a creative profession was bipolar disorder (Kyaga et al., 2013). As one staff member said of the great leader Winston Churchill, “He’s either on the crest of the wave, or in the trough” (Ghaemi, 2011).

It is as true of emotions as of everything else: What goes up comes down. Before long, the elated mood either returns to normal or plunges into a depression. Though bipolar disorder is much less common than major depressive disorder, it is often more dysfunctional, claiming twice as many lost workdays yearly (Kessler et al., 2006). It afflicts adult men and women about equally.

Creativity and bipolar disorder
There have been many creative artists, composers, writers, and musical performers with bipolar disorder.

Actor Russell Brand

Writer Virginia Woolf

Humorist Samuel Clemens (Mark Twain)

Understanding Depressive Disorders and Bipolar Disorder

15-12 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

In thousands of studies, psychologists continue to accumulate evidence to help explain why people have depressive disorders and bipolar disorder and to design more effective ways to treat and prevent them. Here, we focus primarily on depressive disorders. One research group summarized the facts that any theory of depression must explain, including the following (Lewinsohn et al., 1985, 1998, 2003):

- **Many behavioral and cognitive changes accompany depression.** People trapped in a depressed mood become inactive and feel unmotivated. They are sensitive to negative events (Peckham et al., 2010). They more often recall negative information. They expect negative outcomes (my team will lose, my grades will fall, my love will fail). When the depression lifts, these behavioral and cognitive accompaniments disappear. Nearly half the time, people also exhibit symptoms of another disorder, such as anxiety or substance abuse.
- **Depression is widespread.** Worldwide, more than 350 million people suffer depression (WHO, 2012). Although phobias are more common, depression is the number-one reason people seek mental health services. At some point during their lifetime, depression plagues 12 percent of Canadian adults and 17 percent of U.S. adults (Holden, 2010; Patten et al., 2006). Moreover, depression is the leading cause of disability worldwide (Ferrari et al., 2013). Depression's commonality suggests that its causes, too, must be common.
- **Women's risk of major depression is nearly double men's.** In 2009, when Gallup pollsters asked more than a quarter-million Americans if they had ever been diagnosed with depression, 13 percent of men and 22 percent of women said they had (Pelham, 2009). When Gallup asked Americans if they had experienced sadness "during a lot of the day yesterday," 17 percent of men and 28 percent of women answered *Yes* (Mendes & McGeeney, 2012). The depression gender gap has been found worldwide (FIGURE 15.5). The trend begins in adolescence; preadolescent girls are not more depression-prone than are boys (Hyde et al., 2008). With adolescence, girls often think and fret more about their bodies.

The factors that put women at risk for depression (genetic predispositions, child abuse, low self-esteem, marital problems, and so forth) similarly put men at risk (Kendler et al., 2006). Yet women are more vulnerable to disorders involving internalized states, such as depression, anxiety, and inhibited sexual desire. Women experience more situations that may increase their risk for depression, such as receiving less pay for equal work, juggling multiple roles, and caring for children

Life after depression J. K. Rowling, author of the Harry Potter books, reported suffering acute depression—a “dark time,” with suicidal thoughts—between ages 25 and 28. It was a “terrible place,” she said, but it formed a foundation that allowed her “to come back stronger” (McLaughlin, 2010).

▼ FIGURE 15.5 Gender and major depression Interviews with 89,037 adults in 18 countries (10 of which are shown here) confirm what many smaller studies have found: Women's risk of major depression is nearly double that of men's. (Data from Bromet et al., 2011.)

and elderly family members (Freeman & Freeman, 2013). Men's disorders tend to be more external—alcohol use disorder, antisocial conduct, lack of impulse control. When women get sad, they often get sadder than men do. When men get mad, they often get madder than women do.

- **Most major depressive episodes self-terminate.** Therapy often helps and tends to speed recovery. But even without professional help, most people recover from major depression and return to normal. The plague of depression comes and, a few weeks or months later, it goes, though for some (about half), it eventually returns (Burcusa & Iacono, 2007; Curry et al., 2011; Hardeveld et al., 2010). Only about 20 percent experience chronic depression (Klein, 2010). On average, a person with major depressive disorder today will spend about three-fourths of the next decade in a normal, nondepressed state (Furukawa et al., 2009). Recovery is more likely to be permanent the later the first episode strikes, the longer the person stays well, the fewer the previous episodes, the less stress experienced, and the more social support received (Belsher & Costello, 1988; Fergusson & Woodward, 2002; Kendler et al., 2001).
- **Stressful events related to work, marriage, and close relationships often precede depression.** As anxiety is a response to the threat of future loss, depression is often a response to past and current loss. About 1 person in 4 diagnosed with depression has been brought down by a significant loss or trauma, such as a loved one's death, a ruptured marriage, a physical assault, or a lost job (Kendler et al., 2008; Monroe & Reid, 2009; Orth et al., 2009; Wakefield et al., 2007). Minor daily stressors can also leave emotional scars. People who overreacted to minor stressors, such as a broken appliance, were more often depressed 10 years later (Charles et al., 2013). Moving to a new culture can also increase depression, especially among younger people who have not yet formed their identities (Zhang et al., 2013). One long-term study (Kendler, 1998) tracked rates of depression in 2000 people. The risk of depression ranged from less than 1 percent among those who had experienced no stressful life event in the preceding month to 24 percent among those who had experienced three such events in that month.
- **With each new generation, depression strikes earlier (now often in the late teens) and affects more people, with the highest rates in developed countries among young adults.** This trend has been reported in Canada, the United States, England, France, Germany, Italy, Lebanon, New Zealand, Puerto Rico, and Taiwan (Colishaw et al., 2007; Cross-National Collaborative Group, 1992; Kessler et al., 2010; Twenge et al., 2008). In one study, 12 percent of Australian adolescents reported symptoms of depression (Sawyer et al., 2000). Most hid it from their parents; almost 90 percent of those parents perceived their depressed teen as *not* suffering depression. In North America, young adults are three times more likely than their grandparents to report having recently—or ever—suffered depression (despite the grandparents' many more years of being at risk). The increase appears partly authentic, but it may also reflect today's young adults' greater willingness to disclose depression.

“I see depression as the plague of the modern era.”

Lewis Judd, former chief, National Institute of Mental Health, 2000

Armed with these points of understanding, today's researchers propose biological and cognitive explanations of depression, often combined in a biopsychosocial perspective.

The Biological Perspective

Genetic Influences Depressive disorders and bipolar disorder run in families. As one researcher noted, emotions are “postcards from our genes” (Plotkin, 1994). The risk of major depression and bipolar disorder increases if you have a parent or sibling with the disorder (Sullivan et al., 2000). If one identical twin is diagnosed with major

depressive disorder, the chances are about 1 in 2 that at some time the other twin will be, too. This effect is even stronger for bipolar disorder: If one identical twin has it, the chances are 7 in 10 that the other twin will at some point be diagnosed similarly—even if the twins were raised apart (DiLalla et al., 1996). Among fraternal twins, the corresponding odds are just under 2 in 10 (Tsuang & Faraone, 1990). Summarizing the major twin studies (see **FIGURE 15.6**), one research team estimated the heritability of major depressive disorder (the extent to which individual differences are attributable to genes) at 37 percent (Bienvenu et al., 2011).

To tease out the genes that put people at risk for depression, some researchers have turned to *linkage analysis*. First, geneticists find families in which the disorder appears across several generations. Next, the researchers examine DNA from affected and unaffected family members, looking for differences. Linkage analysis points them to a chromosome neighborhood; “A house-to-house search is then needed to find the culprit gene” (Plomin & McGuffin, 2003). Such studies reinforce the view that depression is a complex condition. Many genes work together, producing a mosaic of small effects that interact with other factors to put some people at greater risk. If culprit gene variations can be identified—so far, chromosome 3 genes have been implicated in separate British and American studies (Breen et al., 2011; Pergadia et al., 2011)—they may open the door to more effective drug therapy.

The Depressed Brain Scanning devices open a window on the brain’s activity during depressed and manic states. One study gave 13 elite Canadian swimmers the wrenching experience of watching a video of the swim in which they failed to make the Olympic team or failed at the Olympic games (Davis et al., 2008). Functional MRI scans showed the disappointed swimmers experiencing brain activity patterns similar to those of patients with depressed moods.

Many studies have found diminished brain activity during slowed-down depressive states, and more activity during periods of mania (**FIGURE 15.7**). The left frontal lobe and an adjacent brain reward center become more active during positive emotions, (Davidson et al., 2002; Heller et al., 2009; Robinson et al., 2012). In studies of depressed people, MRI scans also found their frontal lobes were smaller than normal (Coffey et al., 1993; Ribeiz et al., 2013; Steingard et al., 2002). Other studies show that the *hippocampus*, the memory-processing center linked with the brain’s emotional circuitry, is vulnerable to stress-related damage.

Neuroscientists have also discovered altered brain structures in people with bipolar disorder. One analysis discovered decreased white matter and enlarged fluid-filled ventricles (Arnone et al., 2009).

▼ **FIGURE 15.6**
The heritability of various psychological disorders

Researchers Joseph Bienvenu, Dmitry Davydow, and Kenneth Kendler (2011) aggregated data from studies of identical and fraternal twins to estimate the heritability of bipolar disorder, schizophrenia, anorexia nervosa, major depressive disorder, and generalized anxiety disorder.

▼ **FIGURE 15.7**
The ups and downs of bipolar disorder These top-facing PET scans show that brain energy consumption rises and falls with the patient’s emotional switches. Red areas are where the brain rapidly consumes glucose.

Neurotransmitter systems also influence depressive disorders and bipolar disorder. *Norepinephrine*, which increases arousal and boosts mood, is scarce during depression and overabundant during mania. (Drugs that decrease mania reduce norepinephrine.) Many people with a history of depression also have a history of habitual smoking (Pasco et al., 2008). Once the urge to smoke is ignited, depression also makes it more difficult to quit (Hitsman et al., 2012). This may indicate an attempt to self-medicate with inhaled nicotine, which can temporarily increase norepinephrine and boost mood (HMHL, 2002).

Researchers are also exploring a second neurotransmitter, *serotonin* (Carver et al., 2008). One well-publicized study of New Zealand young adults found that the recipe for depression combined two necessary ingredients—significant life stress plus a variation of a serotonin-controlling gene (Caspi et al., 2003; Moffitt et al., 2006). Depression arose from the combination of an adverse environment plus a genetic susceptibility, but not from either alone. But stay tuned: The story of gene-environment interactions is still being written, as other researchers debate the reliability of this result (Caspi et al., 2010; Culverhouse et al., 2013; Karg et al., 2011; Munafò et al., 2009; Uher & McGuffin, 2010).

Drugs that relieve depression tend to increase norepinephrine or serotonin supplies by blocking either their reuptake (as Prozac, Zoloft, and Paxil do with serotonin) or their chemical breakdown. Repetitive physical exercise, such as jogging, reduces depression because it increases serotonin, which affects mood and arousal (Airan et al., 2007; Ilardi, 2009; Jacobs, 1994). In one study, running for two hours increased brain activation in regions associated with euphoria (Boecker et al., 2008). To run away from a bad mood, you can use your own two feet.

Nutritional Effects What’s good for the heart is also good for the brain and mind. People who eat a heart-healthy “Mediterranean diet” (heavy on vegetables, fish, and olive oil) have a comparatively low risk of developing heart disease, stroke, late-life cognitive decline, and depression—all of which are associated with inflammation (Dowlati et al., 2010; Psaltopoulou et al., 2013; Sánchez-Villegas et al., 2009; Tangney et al., 2011). Excessive alcohol use also correlates with depression—mostly because alcohol misuse leads to depression (Fergusson et al., 2009).

The Social-Cognitive Perspective

Biological influences contribute to depression, but in the nature–nurture dance, our actions also play a part. Diet, drugs, stress, and other life experiences lay down *epigenetic marks*, which are often organic molecules. These molecular tags attach to our chromosomes and turn certain genes on or off. Animal studies suggest that epigenetic influences may play a long-lasting role in depression (Nestler, 2011).

Thinking matters, too. The *social-cognitive perspective* explores how people’s assumptions and expectations influence what they perceive. Depressed people view life through the dark glasses of low self-esteem (Kuster et al., 2012; Sowislo & Orth, 2012). Their intensely negative assumptions about themselves, their situation, and their future lead them to magnify bad experiences and minimize good ones (Wenze et al., 2012). Listen to Norman, a Canadian college professor, recalling his depression:

I [despaired] of ever being human again. I honestly felt subhuman, lower than the lowest vermin. Furthermore, I was self-deprecatory and could not understand why anyone would want to associate with me, let alone love me. . . . I was positive that I was a fraud and a phony and that I didn’t deserve my Ph.D. I didn’t deserve to have tenure; I didn’t deserve to be a Full Professor. . . . I didn’t deserve the research grants I had been awarded; I couldn’t understand how I had written books and journal articles. . . . I must have conned a lot of people. (Endler, 1982, pp. 45–49)

Expecting the worst, depressed people’s *self-defeating beliefs* and their *negative explanatory style* feed depression’s vicious cycle.

Negative Thoughts and Negative Moods Interact Self-defeating beliefs may arise from *learned helplessness*, the hopelessness and passive resignation animals and humans learn when they experience uncontrollable painful events. Learned helplessness has been found more often in women than in men, and women may respond more strongly to stress (Hankin & Abramson, 2001; Mazure et al., 2002; Nolen-Hoeksema, 2001, 2003). For example, 38 percent of women and 17 percent of men entering American colleges and universities have reported feeling at least occasionally “overwhelmed by all I have to do” (Pryor et al., 2006). (Men reported spending more time in “light anxiety” activities such as sports, TV watching, and partying, possibly avoiding activities that might make them feel overwhelmed.) This gender difference may help explain why, beginning in their early teens, women have been nearly twice as vulnerable to depression. Susan Nolen-Hoeksema (2003) related women’s higher risk of depression to what she described as their tendency to ruminate or *overthink*. **Rumination**—staying focused on a problem (thanks to the continuous firing of a frontal lobe area that sustains attention)—can be adaptive (Altamirano et al., 2010; Andrews & Thomson, 2009a,b). But relentless, self-focused rumination can divert us from thinking about other life tasks, and can increase negative moods (Kuppens et al., 2010; Kuster et al., 2012).

Even so, why do life’s unavoidable failures lead only some people to become depressed? The answer lies partly in their *explanatory style*—who or what they blame for their failures. Think of how you might feel if you failed a test. If you can externalize the blame (“What an unfair test!”), you are more likely to feel angry. If you blame yourself, you probably will feel stupid and depressed.

So it is with depressed people, who often explain bad events in terms that are *stable* (“It’s going to last forever”), *global* (“It’s going to affect everything I do”), and *internal* (“It’s all my fault”) (FIGURE 15.8). Depression-prone people respond to bad events in an especially self-focused, self-blaming way (Mor & Winquist, 2002; Pyszczynski et al., 1991; Wood et al., 1990a,b). When they describe themselves, their brains activate in a region that processes self-relevant information (Sarsam et al., 2013). Their self-esteem is also more plastic—it climbs with praise and plummets with threats (Butler et al., 1994).

Pessimistic, overgeneralized, self-blaming attributions may create a depressing sense of hopelessness (Abramson et al., 1989; Panzarella et al., 2006). As Martin Seligman has

Michael Marland

Susan Nolen-Hoeksema

(1959–2013) “This epidemic of morbid meditation is a disease that women suffer much more than men. Women can ruminate about anything and everything—our appearance, our families, our career, our health.” (*Women Who Think Too Much: How to Break Free of Overthinking and Reclaim Your Life*, 2003)

rumination compulsive fretting; *overthinking* about our problems and their causes.

▼ FIGURE 15.8

Explanatory style and depression

After a negative experience, a depression-prone person may respond with a negative explanatory style.

"You should never engage in unsupervised introspection."

"Man never reasons so much and becomes so introspective as when he suffers, since he is anxious to get at the cause of his sufferings."

Luigi Pirandello,
Six Characters in Search of an Author, 1922

"Some cause happiness wherever they go; others, whenever they go."

Irish writer Oscar Wilde (1854–1900)

noted, "A recipe for severe depression is preexisting pessimism encountering failure" (1991, p. 78). What then might we expect of new college students who are not depressed but do exhibit a pessimistic explanatory style? In one study, Lauren Alloy and her colleagues (1999) monitored students every 6 weeks for 2.5 years. Among those identified as having a pessimistic thinking style, 17 percent had a first episode of major depression, as did only 1 percent of those who began college with an optimistic thinking style.

Why is depression so common among young Westerners? Seligman (1991, 1995) has pointed to the rise of individualism and the decline of commitment to religion and family, which forces young people to take responsibility for failure or rejection. In non-Western cultures, where close-knit relationships and cooperation are the norm, major depression is less common and less tied to self-blame over personal failure (Ferrari et al., 2013; WHO, 2004a). In Japan, for example, depressed people instead tend to report feeling shame over letting others down (Draguns, 1990a).

Critics note a chicken-and-egg problem nesting in the social-cognitive explanation of depression. Which comes first? The pessimistic explanatory style, or the depressed mood? Certainly, the negative explanations *coincide* with a depressed mood, and they are *indicators* of depression. But do they *cause* depression, any more than a speedometer's reading 70 mph *causes* a car's speed? Before or after being depressed, people's thoughts are less negative. Perhaps a depressed mood triggers negative thoughts. If you temporarily put people in a bad or sad mood, their memories, judgments, and expectations suddenly become more pessimistic. Memory researchers understand this tendency to recall experiences that are consistent with one's current good or bad mood. They call it *state-dependent memory*.

Depression's Vicious Cycle Depression is both a cause and an effect of stressful experiences that disrupt our sense of who we are and why we are worthy human beings. Such disruptions can lead to brooding, which amplifies negative feelings. Being withdrawn, self-focused, and complaining can in turn elicit rejection (Furr & Funder, 1998; Gotlib & Hammen, 1992). One study set up brief phone conversations between participants and people who did or did not have depression. After the conversation, participants could accept or reject the other person. The result? They rejected depression-prone people more often. The participants also noted that they felt more depressed, anxious, and hostile after speaking with depressed people (Coyne, 1976). Indeed, people in the throes of depression are at high risk for divorce, job loss, and other stressful life events. Weary of the person's fatigue, hopeless attitude, and lethargy, a spouse may threaten to leave or a boss may begin to question the person's competence. (This provides another example of genetic-environmental interaction: People genetically predisposed to depression more often experience depressing events.) Rejection and depression feed each other. Misery may love another's company, but company does not love another's misery.

We can now assemble some of the pieces of the depression puzzle (**FIGURE 15.9**): (1) Negative, stressful events interpreted through (2) a ruminating, pessimistic explanatory style create (3) a hopeless, depressed state that (4) hampers the way the person thinks and acts. This, in turn, fuels (1) negative, stressful experiences such as rejection. Depression is a snake that bites its own tail.

None of us are immune to the dejection, diminished self-esteem, and negative thinking brought on by rejection or defeat. Even small losses can temporarily sour our thinking. In one study, researchers studied some avid Indiana University basketball fans who seemed to regard the team as an extension of themselves (Hirt et al., 1992). After the fans watched their team lose or win, the researchers asked them to predict the team's future performance and their own. After a loss, the morose fans offered bleaker assessments not only of the team's future but also of their own likely performance at throwing darts, solving anagrams, and getting a date. When things aren't going our way, it may seem as though they never will.

▼ FIGURE 15.9

The vicious cycle of depressed thinking

Therapists recognize this cycle, and they work to help depressed people break out of it. Each of the bottom three points offers an exit to work toward: 2. Reverse self-blame and a negative outlook. 3. Turn attention outward. 4. Engage in more pleasant activities and more competent behavior.

It is a cycle we can all recognize. Bad moods feed on themselves: When we feel down, we think negatively and remember bad experiences. Abraham Lincoln was so withdrawn and brooding as a young man that his friends feared he might take his own life (Kline, 1974). Poet Emily Dickinson was so afraid of bursting into tears in public that she spent much of her adult life in seclusion (Patterson, 1951). As their lives remind us, people can and do struggle through depression. Most regain their capacity to love, to work, and even to succeed at the highest levels.

Suicide and Self-Injury

15-13 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

Each year over 800,000 despairing people worldwide will elect a permanent solution to what might have been a temporary problem (WHO, 2014). For those who have been depressed, the risk of suicide is at least five times greater than for the general population (Bostwick & Pankratz, 2000). People seldom commit suicide while in the depths of depression, when energy and initiative are lacking. The risk increases when they begin to rebound and become capable of following through.

Comparing the suicide rates of different groups, researchers have found

- **national differences:** Britain's, Italy's, and Spain's suicide rates are little more than half those of Canada, Australia, and the United States. Austria's and Finland's are about double (WHO, 2011). Within Europe, people in the most suicide-prone country (Belarus) have been 16 times more likely to kill themselves than those in the least (Georgia).
- **racial differences:** Within the United States, Whites and Native Americans kill themselves twice as often as Blacks, Hispanics, and Asians (CDC, 2012).
- **gender differences:** Women are much more likely than men to attempt suicide (WHO, 2011). But men are two to four times more likely (depending on the country) to actually end their lives. Men use more lethal methods, such as firing a bullet into the head, the method of choice in 6 of 10 U.S. suicides.
- **age differences and trends:** In late adulthood, rates increase, peaking in middle age and beyond. In the last half of the twentieth century, the global rate of annual suicide deaths nearly doubled (WHO, 2008).
- **other group differences:** Suicide rates have been much higher among the rich, the nonreligious, and those who were single, widowed, or divorced (Hoyer & Lund, 1993; Okada & Samreth, 2013; Stack, 1992; Stengel, 1981). Witnessing physical pain and trauma can increase the risk of suicide, which may help explain physicians' elevated suicide rates (Bender et al., 2012; Cornette et al., 2009). Gay and lesbian

“But life, being weary of these worldly bars, Never lacks power to dismiss itself.”

William Shakespeare, *Julius Caesar*, 1599

youth facing an unsupportive environment, including family or peer rejection, are also at increased risk of attempting suicide (Goldfried, 2001; Haas et al., 2011; Hatzebuehler, 2011). Among people with alcohol use disorder, 3 percent die by suicide. This rate is roughly 100 times greater than the rate for people without alcohol use disorder (Murphy & Wetzel, 1990; Sher, 2006).

- **day of the week differences:** Negative emotion tends to go up midweek, which can have tragic consequences (Watson, 2000). A surprising 25 percent of U.S. suicides occur on Wednesdays (Kposowa & D'Auria, 2009).

Social suggestion may trigger suicide. Following highly publicized suicides and TV programs featuring suicide, known suicides increase. So do fatal auto and private airplane “accidents.” One six-year study tracked suicide cases among all 1.2 million people who lived in metropolitan Stockholm at any time during the 1990s (Hedström et al., 2008). Men exposed to a family suicide were 8 times more likely to commit suicide than were nonexposed men. That phenomenon may be partly attributable to family genes. But shared genetic predispositions cannot explain why men exposed to a co-worker’s suicide were 3.5 times more likely to commit suicide, compared with nonexposed men.

Because suicide is so often an impulsive act, environmental barriers (such as jump barriers on high bridges and the unavailability of loaded guns) can save lives (Anderson, 2008). Common sense may suggest that a determined person will simply find another way to complete the act, but such restrictions give time for self-destructive impulses to subside.

Suicide is not necessarily an act of hostility or revenge. People—especially older adults—may choose death as an alternative to current or future suffering, a way to switch off unendurable pain and relieve a perceived burden on family members. Suicidal urges typically arise when people feel disconnected from others and a burden to them, or when they feel defeated and trapped by an inescapable situation (Joiner, 2010; Taylor et al., 2011). Thus, suicide rates increase a bit during economic recessions (Luo et al., 2011). Suicidal thoughts also may increase when people are driven to reach a goal or standard—to become thin or straight or rich—and find it unattainable (Chatard & Selimbegović, 2011).

In hindsight, families and friends may recall signs they believe should have forewarned them—verbal hints, giving possessions away, or withdrawal and preoccupation with death. To judge from surveys of 84,850 people across 17 nations, about 9 percent of people at some point in their lives have thought seriously of suicide. About 3 in 10 of those who think about it will actually attempt suicide (Nock et al., 2008). Only about 1 in 25 Americans die in that attempt (AAS, 2009). Of those who die, one-third had tried to kill themselves previously. Most discussed it beforehand. So, if a friend talks suicide to you, it’s important to listen and to direct the person to professional help. Anyone who threatens suicide is at least sending a signal of feeling desperate or despondent.

Nonsuicidal Self-Injury Suicide is not the only way to send a message or deal with distress. Some people, especially adolescents and young adults, may engage in *nonsuicidal self-injury* (NSSI) (FIGURE 15.10). These people hurt themselves in various ways. They may cut or burn their skin, hit themselves, insert objects under their nails or skin, or tattoo themselves (Fikke et al., 2011). Though painful, these self-injuries are not fatal. People who engage in NSSI tend to be less able to tolerate emotional distress. They are extremely self-critical and often have poor communication and problem-solving skills (Nock, 2010). Why do they hurt themselves? Through NSSI they may

- find relief from intense negative thoughts through the distraction of pain.
- attract attention and possibly get help.
- relieve guilt by inflicting self-punishment.

▼ **FIGURE 15.10**
Rates of nonfatal self-injury in the U.S. Self-injury rates peak higher for females than for males. (Data from CDC, 2009.)

- get others to change their negative behavior (bullying, criticism).
- fit in with a peer group.

Does NSSI lead to suicide? Usually not. Those who engage in NSSI are typically suicide gesturers, not suicide attempters (Nock & Kessler, 2006). Suicide gesturers engage in NSSI as a desperate but non-life-threatening form of communication or when they are feeling overwhelmed. Nevertheless, NSSI is considered a risk factor for future suicide attempts (Wilkinson & Goodyer, 2011). If people do not find help, their nonsuicidal behavior may escalate to suicidal thoughts and, finally, to suicide attempts.

RETRIEVAL PRACTICE

- What does it mean to say that “depression is a whole-body disorder”?

ANSWER: Many factors contribute to depression, including the biological influences of genetics and brain function. Social-cognitive factors also matter, including the interaction of explanatory style, mood, our responses to stressful experiences, and changes in our patterns of thinking and behaving. The whole body is involved.

“People desire death when two fundamental needs are frustrated to the point of extinction: The need to belong with or connect to others, and the need to feel effective with or to influence others.”

Thomas Joiner (2006, p. 47)

REVIEW Depressive Disorders and Bipolar Disorder

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

15-11 How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

15-12 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

15-13 What factors increase the risk of suicide and what do we know about nonsuicidal self-injury?

TERMS AND CONCEPTS TO REMEMBER

schizophrenia a psychological disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression.

delusion a false belief, often of persecution or grandeur, that may accompany psychotic disorders.

“When someone asks me to explain schizophrenia I tell them, you know how sometimes in your dreams you are in them yourself and some of them feel like real nightmares? My schizophrenia was like I was walking through a dream. But everything around me was real. At times, today’s world seems so boring and I wonder if I would like to step back into the schizophrenic dream, but then I remember all the scary and horrifying experiences.”

Stuart Emmons, with Craig Geiser, Kalman J. Kaplan, and Martin Harrow, *Living With Schizophrenia*, 1997

Art by someone diagnosed with schizophrenia Commenting on the kind of artwork shown here (from Craig Geiser’s 2010 art exhibit in Michigan), poet and art critic John Ashbery wrote: “The lure of the work is strong, but so is the terror of the unanswerable riddles it proposes.”

Schizophrenia

During their most severe periods, people with **schizophrenia** live in a private inner world, preoccupied with the strange ideas and images that haunt them. The word itself means “split” (*schizo*) “mind” (*phrenia*). In this disorder, however, the mind is *not* split into multiple personalities. Rather, the mind has suffered a split from reality that shows itself in disturbed perceptions, disorganized thinking and speech, and diminished, inappropriate emotions. Schizophrenia is the chief example of a *psychosis*, a broad term for a break or split from reality.

Symptoms of Schizophrenia

15-14 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Schizophrenia comes in varied forms. Schizophrenia patients with *positive symptoms* may experience hallucinations, talk in disorganized and deluded ways, and exhibit inappropriate laughter, tears, or rage. Those with *negative symptoms* may have toneless voices, expressionless faces, or mute and rigid bodies.

Disturbed Perceptions

People with schizophrenia sometimes have *hallucinations*—they see, feel, taste, or smell things that exist only in their minds. Most often, the hallucinations are sounds, frequently voices making insulting remarks or giving orders. The voices may tell the person that she is bad or that she must burn herself with a cigarette lighter. Imagine your own reaction if a dream broke into your waking consciousness, making it hard to separate your experience from your imagination. When the unreal seems real, the resulting perceptions are at best bizarre, at worst terrifying.

Disorganized Thinking and Speech

Hallucinations are false *perceptions*. People with schizophrenia also have disorganized, fragmented thinking, which is often distorted by false *beliefs* called **delusions**. If they have *paranoid* tendencies, they may believe they are being threatened or pursued.

Maxine, a young woman with schizophrenia, believed she was Mary Poppins. Communicating with Maxine was difficult because her thoughts spilled out in no logical order. Her biographer, Susan Sheehan (1982, p. 25), observed her saying aloud to no one in particular, “This morning, when I was at Hillside [Hospital], I was making a movie. I was surrounded by movie stars. . . . Is this room painted blue to get me upset? My grandmother died four weeks after my eighteenth birthday.”

Jumbled ideas may make no sense even within sentences, forming what is known as *word salad*. One young man begged for “a little more allegro in the treatment,” and suggested that “liberationary movement with a view to the widening of the horizon” will “ergo extort some wit in lectures.”

One cause of disorganized thinking may be a breakdown in *selective attention*. Normally, we have a remarkable capacity for giving our undivided attention to one set of sensory stimuli while filtering out others. People with schizophrenia cannot do this. Thus, tiny, irrelevant stimuli, such as the grooves on a brick or the inflections of a voice, may distract their attention from a bigger event or a speaker’s meaning. As one former patient recalled, “What had happened to me . . . was a breakdown in the filter, and a hodge-podge of unrelated stimuli were distracting me from things which should have had my undivided attention” (MacDonald, 1960, p. 218). This selective attention difficulty is but one of dozens of cognitive differences associated with schizophrenia (Reichenberg & Harvey, 2007).

Diminished and Inappropriate Emotions

The expressed emotions of schizophrenia are often utterly inappropriate, split off from reality (Kring & Caponigro, 2010). Maxine laughed after recalling her grandmother's death. On other occasions, she cried when others laughed, or became angry for no apparent reason. Others with schizophrenia lapse into an emotionless *flat affect* state of no apparent feeling. Most also have an *impaired theory of mind*—they have difficulty perceiving facial emotions and reading others' states of mind (Green & Horan, 2010; Kohler et al., 2010). These deficiencies occur early in the illness and have a genetic basis (Bora & Pantelis, 2013).

Motor behavior may also be inappropriate. Some perform senseless, compulsive acts, such as continually rocking or rubbing an arm. Others may remain motionless for hours (a condition called *catatonia*) and then become agitated.

As you can imagine, such disturbed perceptions, disorganized thinking, and inappropriate emotions profoundly disrupt social and work relationships. During their most severe periods, people with schizophrenia live in a private inner world, preoccupied with illogical ideas and unreal images. Many have sleep problems, which can increase night eating and obesity (Palmese et al., 2011). Given a supportive environment and medication, over 40 percent of people with schizophrenia will have periods of a year or more of normal life experience (Jobe & Harrow, 2010). Many others remain socially withdrawn and isolated or rejected for much of their lives (Hooley, 2010).

Onset and Development of Schizophrenia

15-15 How do chronic and acute schizophrenia differ?

Nearly 1 in 100 people will experience schizophrenia this year, joining the estimated 24 million worldwide who have this disorder (Abel et al., 2010; WHO, 2011). It typically strikes as young people are maturing into adulthood. It knows no national boundaries, and it affects both males and females. Men tend to be struck earlier, more severely, and slightly more often (Aleman et al., 2003; Eranti et al., 2013; Picchioni & Murray, 2007). The risk of schizophrenia is higher for those who experience childhood abuse: They are three times more likely than their unabused counterparts to develop this disorder (Matheson et al., 2013). Other types of childhood adversity, such as bullying, also increase the risk (Varese et al., 2012).

When schizophrenia is a slow-developing process, called **chronic schizophrenia**, recovery is doubtful (WHO, 1979). This was the case with Maxine's schizophrenia, which took a slow course, emerging from a long history of social inadequacy and poor school performance (MacCabe et al., 2008). Those with chronic schizophrenia often exhibit the persistent and incapacitating negative symptom of social withdrawal (Kirkpatrick et al., 2006). Men, whose schizophrenia develops on average four years earlier than women's, more often exhibit negative symptoms and chronic schizophrenia (Räsänen et al., 2000). In one study that followed people with chronic schizophrenia over 34 years, the majority showed worsened symptoms and functioning (Newman et al., 2012).

When previously well-adjusted people develop schizophrenia rapidly following particular life stresses, this is called **acute schizophrenia**, and recovery is much more likely. They more often have the positive symptoms that are more likely to respond to drug therapy (Fenton & McGlashan, 1991, 1994; Fowles, 1992).

Understanding Schizophrenia

Schizophrenia is a dreaded psychological disorder. It is also one of the most heavily researched. Most studies now link it with abnormal brain tissue and genetic predispositions. Schizophrenia is a disease of the brain manifested in symptoms of the mind.

chronic schizophrenia (also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As people age, psychotic episodes last longer and recovery periods shorten.

acute schizophrenia (also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age, frequently occurs in response to an emotionally traumatic event, and has extended recovery periods.

Brain Abnormalities

15-16 What brain abnormalities are associated with schizophrenia?

Might chemical imbalances in the brain underlie schizophrenia? Scientists have long known that strange behavior can have strange chemical causes. The saying “mad as a hatter” refers to the psychological deterioration of British hatmakers whose brains, it was later discovered, were slowly poisoned as they moistened the brims of mercury-laden felt hats with their tongue and lips (Smith, 1983). Could schizophrenia symptoms have a similar biochemical key? Scientists continue to track the mechanisms by which chemicals produce hallucinations and other symptoms.

Dopamine Overactivity One possible answer emerged when researchers examined schizophrenia patients’ brains after death. They found an excess of receptors for *dopamine*—a sixfold excess for the dopamine receptor D4 (Seeman et al., 1993; Wong et al., 1986). Such a hyper-responsive dopamine system may intensify brain signals in schizophrenia, creating positive symptoms such as hallucinations and paranoia (Grace, 2010). Drugs that block dopamine receptors often lessen these symptoms. Drugs that increase dopamine levels, such as amphetamines and cocaine, sometimes intensify them (Seeman, 2007; Swerdlow & Koob, 1987).

Abnormal Brain Activity and Anatomy Brain scans show that abnormal activity accompanies schizophrenia. Some people diagnosed with schizophrenia have abnormally low brain activity in the frontal lobes, areas that help us reason, plan, and solve problems (Morey et al., 2005; Pettegrew et al., 1993; Resnick, 1992). Brain scans also show a noticeable decline in the brain waves that reflect synchronized neural firing in the frontal lobes (Spencer et al., 2004; Symond et al., 2005). Out-of-sync neurons may disrupt the integrated functioning of neural networks, possibly contributing to schizophrenia symptoms.

One study took PET scans of brain activity while people were hallucinating (Silbersweig et al., 1995). When participants heard a voice or saw something, their brain became vigorously active in several core regions. One was the thalamus, the structure that filters incoming sensory signals and transmits them to the brain’s cortex. Another PET scan study of people with paranoia found increased activity in the amygdala, a fear-processing center (Epstein et al., 1998).

Many studies have found enlarged, fluid-filled areas and a corresponding shrinkage and thinning of cerebral tissue in people with schizophrenia (Goldman et al., 2009; Wright et al., 2000). People often inherit these brain differences. If one affected identical twin shows brain abnormalities, the odds are at least 1 in 2 that the other twin will have them (van Haren et al., 2012). Even people who will *later* develop the disorder may show these symptoms (Karlsgodt et al., 2010). The greater the brain shrinkage, the more severe the thought disorder (Collinson et al., 2003; Nelson et al., 1998; Shenton, 1992).

Two smaller-than-normal areas are the cortex and the corpus callosum connecting the brain’s two hemispheres (Arnone et al., 2008). Another is the thalamus, which may explain why people with schizophrenia have difficulty filtering sensory input and focusing attention (Andreasen et al., 1994; Ellison-Wright et al., 2008). The bottom line is that schizophrenia involves not one isolated brain abnormality but problems with several brain regions and their interconnections (Andreasen, 1997, 2001).

Prenatal Environment and Risk

15-17 What prenatal events are associated with increased risk of developing schizophrenia?

What causes brain abnormalities in people with schizophrenia? Some scientists point to mishaps during prenatal development or delivery (Fatemi & Folsom, 2009; Walker et al., 2010). Risk factors for schizophrenia include low birth weight, maternal diabetes,

Most people with schizophrenia smoke, often heavily. Nicotine apparently stimulates certain brain receptors, which helps focus attention (Diaz et al., 2008; Javitt & Coyle, 2004).

older paternal age, and oxygen deprivation during delivery (King et al., 2010). Famine may also increase risks. People conceived during the peak of World War II's Dutch wartime famine later developed schizophrenia at twice the normal rate. Those conceived during the famine of 1959 to 1961 in eastern China also displayed this doubled rate (St. Clair et al., 2005; Susser et al., 1996).

Let's consider another possible culprit. Might a midpregnancy viral infection impair fetal brain development (Brown & Patterson, 2011)? Can you imagine some ways to test this fetal-virus idea? Scientists have asked the following:

- *Are people at increased risk of schizophrenia if, during the middle of their fetal development, their country experienced a flu epidemic?* The repeated answer has been *Yes* (Mednick et al., 1994; Murray et al., 1992; Wright et al., 1995).
- *Are people born in densely populated areas, where viral diseases spread more readily, at greater risk for schizophrenia?* The answer, confirmed in a study of 1.75 million Danes, has again been *Yes* (Jablensky, 1999; Mortensen, 1999).
- *Are those born during the winter and spring months—after the fall-winter flu season—also at increased risk?* Although the increase is small, just 5 to 8 percent, the answer has been *Yes* (Fox, 2010; Schwartz, 2011; Torrey et al., 1997, 2002).
- *In the Southern Hemisphere, where the seasons are the reverse of the Northern Hemisphere, are the months of above-average schizophrenia births similarly reversed?* Again, the answer has been *Yes*, though somewhat less so. In Australia, people born between August and October are at greater risk. But there is an exception: For people born in the Northern Hemisphere, who later moved to Australia, the risk is greater if they were born between January and March (McGrath et al., 1995, 1999).
- *Are mothers who report being sick with influenza during pregnancy more likely to bear children who develop schizophrenia?* In one study of nearly 8000 women, the answer was *Yes*. The schizophrenia risk increased from the customary 1 percent to about 2 percent—but only when infections occurred during the second trimester (Brown et al., 2000). Maternal influenza infection during pregnancy affects brain development in monkeys also (Short et al., 2010).
- *Does blood drawn from pregnant women whose offspring develop schizophrenia show higher-than-normal levels of antibodies that suggest a viral infection?* In one study of 27 women whose children later developed schizophrenia, the answer was *Yes* (Buka et al., 2001). And the answer was again *Yes* in a huge California study, which collected blood samples from some 20,000 pregnant women during the 1950s and 1960s (Brown et al., 2004). Another study found traces of a specific retrovirus (HERV) in nearly half of people with schizophrenia and virtually none in healthy people (Perron et al., 2008).

These converging lines of evidence suggest that fetal-virus infections contribute to the development of schizophrenia. They also strengthen the U.S. government recommendation that “pregnant women need a flu shot” (CDC, 2014).

Why might a second-trimester maternal flu bout put a fetus at risk? Is the virus itself the culprit? The mother's immune response to it? Medications taken (Wyatt et al., 2001)? Does the infection weaken the brain's supportive glial cells, leading to reduced synaptic connections (Moises et al., 2002)? In time, answers may become available.

Genetic Factors

15-18 Do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Fetal-virus infections may increase the odds that a child will develop schizophrenia. But many women get the flu during their second trimester of pregnancy, and only 2 percent of them bear children who develop schizophrenia. Why are only some children at risk?

▼ FIGURE 15.11

Risk of developing schizophrenia The lifetime risk of developing schizophrenia varies with one's genetic relatedness to someone having this disorder. Across countries, barely more than 1 in 10 fraternal twins, but some 5 in 10 identical twins, share a schizophrenia diagnosis. (Data from Gottesman, 2001.)

Schizophrenia risk for twins of those diagnosed with schizophrenia

Might some people be more vulnerable because they inherit a predisposition to this disorder? Some people with no family history of schizophrenia develop the disorder (Xu et al., 2011). But the evidence strongly suggests that, Yes, some may inherit a predisposition to schizophrenia. The nearly 1-in-100 odds of any person's being diagnosed with schizophrenia become about 1 in 10 among those who have a sibling or parent with the disorder. If the affected sibling is an identical twin, the odds increase to nearly 5 in 10 (FIGURE 15.11). Those odds remain the same even when the twins are raised apart (Plomin et al., 1997). (Only about a dozen such cases are on record.)

Remember, though, that identical twins share more than their genes. They also share a prenatal environment. About two-thirds share a placenta and the blood it supplies; the other one-third have separate placentas. Shared placentas matter. If the co-twin of an identical twin with schizophrenia shared the placenta, the chances of developing the disorder are 6 in 10. If the identical twins had separate placentas (as do fraternal twins), the co-twin's chances of developing schizophrenia drop to 1 in 10 (Davis et al., 1995a,b; Phelps et al., 1997). Twins who share a placenta are more likely to share the same prenatal viruses. So perhaps shared germs as well as shared genes produce identical twin similarities.

Adoption studies help untangle genetic and environmental influences. Children adopted by someone who develops schizophrenia seldom “catch” the disorder. Rather, adopted children have an elevated risk if a *biological* parent is diagnosed with schizophrenia (Gottesman, 1991).

The search is on for specific genes that, in some combination, predispose schizophrenia-inducing brain abnormalities (Levinson et al., 2011; Mitchell & Porteous, 2011; Ripke et al., 2011; Vacic et al., 2011). (It is not our genes but our brains that directly control our behavior.) Some of these genes influence the effects of dopamine and other neurotransmitters in the brain. Others affect the production of *myelin*, a fatty substance that coats the axons of nerve cells and lets impulses travel at high speed through neural networks.

Schizophrenia in identical twins

When twins differ, only the one afflicted with schizophrenia typically has enlarged, fluid-filled cranial cavities (right) (Suddath et al., 1990). The difference between the twins implies some nongenetic factor, such as a virus, is also at work.

No schizophrenia

Schizophrenia

Although genes matter, the genetic formula is not as straightforward as the inheritance of eye color. Genome studies of thousands of individuals with and without schizophrenia indicate that schizophrenia is influenced by many genes, each with very small effects (International Schizophrenia Consortium, 2009; Xu et al., 2012). And, as we have so often seen, nature and nurture interact. *Epigenetic* (literally “in addition to genetic”) factors influence whether or not genes will be expressed. Like hot water activating a tea bag, environmental factors such as viral infections, nutritional deprivation, and maternal stress can “turn on” the genes that put some of us at higher risk for schizophrenia. Identical twins' differing histories in the womb and beyond explain why only

one of them may show differing gene expressions (Dempster et al., 2013; Walker et al., 2010). Our heredity and our life experiences work together. Neither hand claps alone.

Thanks to our expanding understanding of genetic and brain influences on maladies such as schizophrenia, the general public more and more attributes psychiatric disorders to biological factors (Pescosolido et al., 2010). In 2007, one privately funded new research center announced its ambitious aim: “To unambiguously diagnose patients with psychiatric disorders based on their DNA sequence in 10 years’ time” (Holden, 2007). In 2010, \$120 million in start-up funding launched a bold new effort to study the neuroscience and genetics of schizophrenia and other psychiatric disorders (Kaiser, 2010). So, can scientists develop genetic tests that reveal who is at risk? If so, will people in the future subject their embryos to genetic testing (and gene repair or abortion) if they are at risk for this or some other psychological or physical malady? Might they take their egg and sperm to a genetics lab for screening before combining them to produce an embryo? Or will children be tested for genetic risks and given appropriate preventive treatments? In this brave new twenty-first-century world, such questions await answers.

Environmental Triggers for Schizophrenia

If prenatal viruses and genetic predispositions do not, by themselves, cause schizophrenia, neither do family or social factors alone. It remains true, as Susan Nicol and Irving Gottesman (1983) noted over three decades ago, that “no environmental causes have been discovered that will invariably, or even with moderate probability, produce schizophrenia in persons who are not related to” a person with schizophrenia.

Hoping to identify environmental triggers of schizophrenia, researchers have compared the experiences of high-risk children (for example, those with relatives with schizophrenia) and low-risk children. In one 2.5-year study that followed 163 teens and early-twenties adults who had two relatives with schizophrenia, the 20 percent of participants who developed schizophrenia showed social withdrawal or other abnormal behavior before the onset of the disorder (Johnstone et al., 2005). Researchers (Abel et al., 2010; Freedman et al., 1998; Schiffman et al., 2001; Susser, 1999; Welham et al., 2009) identified these other possible early warning signs:

- A mother whose schizophrenia was severe and long-lasting
- Birth complications, often involving oxygen deprivation and low birth weight
- Separation from parents
- Short attention span and poor muscle coordination
- Disruptive or withdrawn behavior
- Emotional unpredictability
- Poor peer relations and solo play
- Childhood physical, sexual, or emotional abuse

* * *

Few of us can relate to the strange thoughts, perceptions, and behaviors of schizophrenia. Sometimes our thoughts jump around, but we rarely talk nonsensically. Occasionally we feel unjustly suspicious of someone, but we do not fear that the world is plotting against us. Often our perceptions err, but rarely do we see or hear things that are not there. We feel regret after laughing at someone’s misfortune, but we rarely giggle in response to bad news. At times we just want to be alone, but we do not live in social isolation. However, millions of people around the world do talk strangely, suffer delusions, hear nonexistent voices, see things that are not there, laugh or cry at inappropriate times, or withdraw into private imaginary worlds. The quest to solve the cruel puzzle of schizophrenia continues, more vigorously than ever.

HOW WOULD YOU KNOW?

Consider how researchers have studied these issues with LaunchPad’s *How Would You Know If Schizophrenia is Inherited?*

LaunchPad For an 8-minute description of how clinicians define and treat schizophrenia, visit LaunchPad's *Video—Schizophrenia: New Definitions, New Therapies*.

RETRIEVAL PRACTICE

- A person with schizophrenia who has _____ (positive/negative) symptoms may have an expressionless face and toneless voice. These symptoms are most common with _____ (chronic/acute) schizophrenia and are not likely to respond to drug therapy. Those with _____ (positive/negative) symptoms are likely to experience delusions and to be diagnosed with _____ (chronic/acute) schizophrenia, which is much more likely to respond to drug therapy.

ANSWERS: negative; chronic; positive; acute

- What factors contribute to the onset and development of schizophrenia?

ANSWER: Biological factors include abnormalities in brain structure and function, prenatal exposure to a maternal virus, and a genetic predisposition to the disorder. However, a high-risk environment, with many environmental triggers, can increase the odds of developing schizophrenia.

REVIEW Schizophrenia

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

15-14 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

15-15 How do chronic and acute schizophrenia differ?

15-16 What brain abnormalities are associated with schizophrenia?

15-17 What prenatal events are associated with increased risk of developing schizophrenia?

15-18 Do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Dissociative, Personality, and Eating Disorders

Dissociative Disorders

15-19 What are dissociative disorders, and why are they controversial?

Among the most bewildering disorders are the rare **dissociative disorders**, in which a person's conscious awareness *dissociates* (separates) from painful memories, thoughts, and feelings. The result may be a *fugue state*, a sudden loss of memory or change in identity, often in response to an overwhelmingly stressful situation. Such was the case for one Vietnam veteran who was haunted by his comrades' deaths, and who had left his World Trade Center office shortly before the 9/11 attack. Later, he disappeared on

dissociative disorders controversial, rare disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings.

the way to work. Six months later, when he was discovered in a Chicago homeless shelter, he reported no memory of his identity or family (Stone, 2006).

Dissociation itself is not so rare. Any one of us may have a sense of being unreal, of being separated from our body, of watching ourselves as if in a movie. Sometimes we may say, “I was not myself at the time.” Perhaps you can recall getting up to go somewhere and ending up at some unintended location while your mind was preoccupied. Or perhaps you can play a well-practiced tune on a guitar or piano while talking to someone. When we face trauma, dissociative detachment may protect us from being overwhelmed by emotion.

Dissociative Identity Disorder

A massive dissociation of self from ordinary consciousness occurs in **dissociative identity disorder (DID)**, in which two or more distinct identities—each with its own voice and mannerisms—seem to control a person’s behavior at different times. Thus, the person may be prim and proper one moment, loud and flirtatious the next. Typically, the original personality denies any awareness of the other(s).

People diagnosed with DID (formerly called *multiple personality disorder*) are rarely violent. But cases have been reported of dissociations into a “good” and a “bad” (or aggressive) personality—a modest version of the Dr. Jekyll–Mr. Hyde split immortalized in Robert Louis Stevenson’s story. One unusual case involved Kenneth Bianchi, accused in the “Hillside Strangler” rapes and murders of 10 California women. During a hypnosis session, Bianchi’s psychologist “called forth” a hidden personality: “I’ve talked a bit to Ken, but I think that perhaps there might be another part of Ken that . . . maybe feels somewhat differently from the part that I’ve talked to. . . . Would you talk with me, Part, by saying, ‘I’m here?’” Bianchi answered “Yes” and then claimed to be “Steve” (Watkins, 1984).

Speaking as Steve, Bianchi stated that he hated Ken because Ken was nice and that he (Steve), aided by a cousin, had murdered women. He also claimed Ken knew nothing about Steve’s existence and was innocent of the murders. Was Bianchi’s second personality a trick, simply a way of disavowing responsibility for his actions? Indeed, Bianchi—a practiced liar who had read about multiple personality in psychology books—was later convicted.

Understanding Dissociative Identity Disorder

Skeptics have raised serious concerns about DID. First, instead of being a true disorder, could DID be an extension of our normal capacity for personality shifts? Nicholas Spanos (1986, 1994, 1996) asked college students to pretend they were accused murderers being examined by a psychiatrist. Given the same hypnotic treatment Bianchi received, most spontaneously expressed a second personality. This discovery made Spanos wonder: Are dissociative identities simply a more extreme version of our capacity to vary the “selves” we present—as when we display a goofy, loud self while hanging out with friends, and a subdued, respectful self around grandparents? Are clinicians who discover multiple personalities merely triggering role playing by fantasy-prone people? Do these patients, like actors who commonly report “losing themselves” in their roles, then convince themselves of the authenticity of their own role enactments? Spanos was no stranger to this line of thinking. In a related research area, he had also raised these questions about the hypnotic state. Because most DID patients are highly hypnotizable, whatever explains one condition—dissociation or role playing—may help explain the other.

Skeptics also find it suspicious that the disorder has such a short and localized history. Between 1930 and 1960, the number of North American DID diagnoses averaged 2 per decade. By the 1980s, when the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders* (DSM) contained the first formal code for

Multiple personalities Chris Sizemore’s story, told in the book and movie, *The Three Faces of Eve*, gave early visibility to what is now called *dissociative identity disorder*.

The “Hillside Strangler” Kenneth Bianchi is shown here at his trial.

“Pretense may become reality.”

Chinese proverb

dissociative identity disorder (DID) a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. Formerly called *multiple personality disorder*.

The Mankato Free Press/AP Photo

Widespread dissociation Shirley Mason was a psychiatric patient diagnosed with dissociative identity disorder. Her life formed the basis of the bestselling book, *Sybil* (Schreiber, 1973), and of two movies. Some argue that the book and movies' popularity fueled the dramatic rise in diagnoses of dissociative identity disorder. Skeptics wonder whether she actually had dissociative identity disorder (Nathan, 2011).

"Though this be madness, yet there is method in 't."

"Would it be possible to speak with the personality that pays the bills?"

this disorder, the number exploded to more than 20,000 (McHugh, 1995a). The average number of displayed personalities also mushroomed—from 3 to 12 per patient (Goff & Simms, 1993). This disorder is much less prevalent outside North America, although in other cultures people may be said to be “possessed” by an alien spirit (Aldridge-Morris, 1989; Kluft, 1991). In Britain, DID—which some have considered “a wacky American fad” (Cohen, 1995)—is rare. In India and Japan, it is essentially nonexistent (or at least unreported).

Such findings, skeptics note, point to a cultural phenomenon—a disorder created by therapists in a particular social context (Merskey, 1992). Rather than being provoked by trauma, dissociative symptoms tend to be exhibited by suggestible, fantasy-prone people (Giesbrecht et al., 2008, 2010). Patients do not enter therapy saying “Allow me to introduce myself.” Instead, charge the critics, some therapists go fishing for multiple personalities: “*Have you ever felt like another part of you does things you can’t control? Does this part of you have a name? Can I talk to the angry part of you?*” Once patients permit a therapist to talk, by name, “to the part of you that says those angry things,” they begin acting out the fantasy. The result may be the experience of another self.

Other researchers and clinicians believe DID is a real disorder. They find support for this view in the distinct body and brain states associated with differing personalities (Putnam, 1991). Handedness sometimes switches with personality (Henninger, 1992). Shifts in visual acuity and eye-muscle balance have been recorded as patients switched personalities, but not as control group members tried to simulate DID behavior (Miller et al., 1991). Abnormal brain anatomy and activity can also accompany DID. Brain scans show shrinkage in areas that aid memory and detection of threat (Vermetten et al., 2006). Heightened activity appears in brain areas associated with the control and inhibition of traumatic memories (Elzinga et al., 2007).

Both the psychodynamic and learning perspectives have interpreted DID symptoms as ways of coping with anxiety. Some psychodynamic theorists see them as defenses against the anxiety caused by the eruption of unacceptable impulses. In this view, a second personality enables the discharge of forbidden impulses. Learning theorists see dissociative disorders as behaviors reinforced by anxiety reduction.

Some clinicians include dissociative disorders under the umbrella of posttraumatic stress disorder—a natural, protective response to traumatic experiences during childhood (Putnam, 1995; Spiegel, 2008). Many DID patients recall being physically, sexually, or emotionally abused as children (Gleaves, 1996; Lilienfeld et al., 1999). In one study of 12 murderers diagnosed with DID, 11 had suffered severe, torturous child abuse (Lewis et al., 1997). One had been set afire by his parents. Another had been used in child pornography and was scarred from being made to sit on a stove burner. Some critics wonder, however, whether vivid imagination or therapist suggestion contributed to such recollections (Kihlstrom, 2005).

So the debate continues. On one side are those who believe multiple personalities are the desperate efforts of people trying to detach from a horrific existence. On the other are the skeptics who think DID is a condition constructed out of the therapist-patient interaction and acted out by fantasy-prone, emotionally vulnerable people. If the skeptics’ view wins, predicted psychiatrist Paul McHugh (1995b), “this epidemic will end in the way that the witch craze ended in Salem. The [multiple personality phenomenon] will be seen as manufactured.”

RETRIEVAL PRACTICE

- The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their explanations differ?

ANSWER: The psychodynamic explanation of DID symptoms is that they are defenses against anxiety generated by unacceptable urges. The learning perspective attempts to explain these symptoms as behaviors that have been reinforced by relieving anxiety in the past.

Personality Disorders

15-20 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

The disruptive, inflexible, and enduring behavior patterns of **personality disorders** interfere with social functioning. These disorders tend to form three clusters, characterized by

- anxiety, such as a fearful sensitivity to rejection that predisposes the withdrawn *avoidant personality disorder*.
- eccentric or odd behaviors, such as the emotionless disengagement of *schizotypal personality disorder*.
- dramatic or impulsive behaviors, such as the attention-getting *borderline personality disorder*, the self-focused and self-inflating *narcissistic personality disorder*, and the callous, and sometimes dangerous, *antisocial personality disorder*.

Antisocial Personality Disorder

A person with **antisocial personality disorder** is typically a male whose lack of conscience becomes plain before age 15, as he begins to lie, steal, fight, or display unrestrained sexual behavior (Cale & Lilienfeld, 2002). About half of such children become antisocial adults—unable to keep a job, irresponsible as a spouse and parent, and assaultive or otherwise criminal (Farrington, 1991). (These people are sometimes called *sociopaths* or *psychopaths*.) They may show lower *emotional intelligence*—the ability to understand, manage, and perceive emotions (Ermer et al., 2012). When the antisocial personality combines a keen intelligence with amorality, the result may be a charming and clever con artist—or even a fearless, focused, ruthless soldier, CEO, or politician (Dutton, 2012).

Despite their remorseless and sometimes criminal behavior, criminality is not an essential component of antisocial behavior (Skeem & Cooke, 2010). Moreover, many criminals do not fit the description of antisocial personality disorder. Why? Because they actually show responsible concern for their friends and family members.

Antisocial personalities behave impulsively, and then feel and fear little (Fowles & Dindo, 2009). Their impulsivity can have violent, horrifying consequences (Camp et al., 2013). Consider the case of Henry Lee Lucas. He killed his first victim when he was 13. He felt little regret then or later. He confessed that, during his 32 years of crime, he had brutally beaten, suffocated, stabbed, shot, or mutilated some 360 women, men, and children. For the last six years of his reign of terror, Lucas teamed with Ottis Elwood Toole, who reportedly slaughtered about 50 people he “didn’t think was worth living anyhow” (Darrach & Norris, 1984).

Understanding Antisocial Personality Disorder

Antisocial personality disorder is woven of both biological and psychological strands. Twin and adoption studies reveal that biological relatives of people with antisocial and unemotional tendencies are at increased risk for antisocial behavior (Frisell et al., 2012; Tuvblad et al., 2011). No single gene codes for a complex behavior such as crime. Molecular geneticists have, however, identified some specific genes that are more common in those with antisocial personality disorder (Gunter et al., 2010). The genetic vulnerability of people with antisocial and unemotional tendencies appears as a fearless approach to life. Awaiting aversive events, such as electric shocks or loud noises, they show little autonomic nervous system arousal (Hare, 1975; van Goozen et al., 2007). Long-term studies have shown that their levels of stress hormones were lower than average when

No remorse Dennis Rader, known as the “BTK killer” in Kansas, was convicted in 2005 of killing 10 people over a 30-year span. Rader exhibited the extreme lack of conscience that marks antisocial personality disorder.

“Thursday is out. I have jury duty.”

Many criminals, like this one, exhibit a sense of conscience and responsibility in other areas of their life, and thus do not exhibit antisocial personality disorder.

personality disorders inflexible and enduring behavior patterns that impair social functioning.

antisocial personality disorder a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist.

▼ FIGURE 15.12

Cold-blooded arousability and risk of crime

Levels of the stress hormone adrenaline were measured in two groups of 13-year-old Swedish boys. In both stressful and nonstressful situations, those who would later be convicted of a crime as 18- to 26-year-olds showed relatively low arousal. (Data from Magnusson, 1990.)

Does a full Moon trigger “madness” in some people? James Rotton and I. W. Kelly (1985) examined data from 37 studies that related lunar phase to crime, homicides, crisis calls, and mental hospital admissions. Their conclusion: There is virtually no evidence of “Moon madness.” Nor does lunar phase correlate with suicides, assaults, emergency room visits, or traffic disasters (Martin et al., 1992; Raison et al., 1999).

▼ FIGURE 15.13

Murderous minds

Researchers have found reduced activation in a murderer’s frontal lobes. This brain area (shown in a left-facing brain) helps brake impulsive, aggressive behavior (Raine, 1999).

they were youngsters, before committing any crime (FIGURE 15.12). Three-year-olds who are slow to develop conditioned fears are later more likely to commit a crime (Gao et al., 2010). Other studies have found that preschool boys who later became aggressive or antisocial adolescents tended to be impulsive, uninhibited, unconcerned with social rewards, and low in anxiety (Caspi et al., 1996; Tremblay et al., 1994).

Traits such as fearlessness and dominance can be adaptive. In fact, some argue that psychopaths and heroes are twigs off the same branch (Smith et al., 2013). If channeled in more productive directions, fearlessness may lead to star-level athleticism, adventurism, or courageous heroism (Poulton & Milne, 2002). One analysis of 42 American presidents showed that they scored higher than the general population on such traits as fearlessness and dominance (Lilienfeld et al., 2012). Consistent with evidence that such traits can run in families, two of the most fearless and dominant presidents were distant cousins with the same last name: Roosevelt. (Two of the least fearless and dominant presidents were a father and son, John Adams and John Quincy Adams.) Lacking a sense of social responsibility, the same disposition may produce a cool con artist or killer (Lykken, 1995).

Genetic influences, often in combination with child abuse, help wire the brain (Dodge, 2009). In people with antisocial criminal tendencies, the emotion-controlling amygdala is smaller (Pardini et al., 2013; Yang et al., 2010). The frontal lobes are also less active, as Adrian Raine (1999, 2005) found when he compared PET scans of 41 murderers’ brains with those from people of similar age and sex (FIGURE 15.13). This area of the cortex helps control impulses. The reduced activation was especially apparent in those who murdered impulsively. In a follow-up study, Raine and his team (2000) found that violent repeat offenders had 11 percent less frontal lobe tissue than normal. This helps explain why people with antisocial personality disorder exhibit marked deficits in frontal lobe cognitive functions, such as planning, organization, and inhibition (Morgan & Lilienfeld, 2000). Compared with people who feel and display empathy, their brains also respond less to facial displays of others’ distress, which may contribute to their lower emotional intelligence (Deeley et al., 2006).

A biologically based fearlessness, as well as early environment, helps explain the reunion of long-separated sisters Joyce Lott, 27, and Mary Jones, 29—in a South Carolina prison where both were sent on drug charges. After a newspaper story about their reunion, their long-lost half-brother Frank Strickland called. He explained it would be a while before he could come see them—because he, too, was in jail, on drug, burglary, and larceny charges (Shepherd et al., 1990). The genes that put people at risk for antisocial behavior also put people at risk for substance use disorders, which may help explain why these disorders often appear in combination (Dick, 2007).

Genetics alone do not tell the whole story of antisocial crime, however. In another

Raine-led study (1996), researchers checked criminal records on nearly 400 Danish men at ages 20 to 22. All these men either had experienced biological risk factors at birth (such as premature birth) or came from family backgrounds marked by poverty and family instability. The researchers then compared each of these two groups with a third *biosocial* group (people whose lives were marked by *both* those biological and social risk factors). The biosocial group had double the risk of committing crime (FIGURE 15.14). Similar findings emerged from a famous study that followed 1037 children for a quarter-century: Two combined factors—childhood maltreatment and a gene that altered

neurotransmitter balance—predicted antisocial problems (Caspi et al., 2002). Neither “bad” genes alone nor a “bad” environment alone predisposed later antisocial behavior. Rather, genes predisposed some children to be more sensitive to maltreatment. Within “genetically vulnerable segments of the population,” environmental influences matter—for better or for worse (Belsky et al., 2007; Moffitt, 2005; Pluess & Belsky, 2013).

With antisocial behavior, as with so much else, nature and nurture interact and the biopsychosocial perspective helps us understand the whole story. To explore the neural basis of antisocial personality disorder, neuroscientists are trying to identify brain activity differences in criminals who display symptoms of this disorder. Shown emotionally evocative photographs, such as a man holding a knife to a woman’s throat, criminals with antisocial personality disorder display blunted heart rate and perspiration responses, and less activity in brain areas that typically respond to emotional stimuli (Harenski et al., 2010; Kiehl & Buckholtz, 2010). They also have a larger and hyper-reactive dopamine reward system, which predisposes their impulsive drive to do something rewarding despite the consequences (Buckholtz et al., 2010; Glenn et al., 2010). Such data provide another reminder: Everything psychological is also biological.

▼ FIGURE 15.14

Biopsychosocial roots of crime

Danish male babies whose backgrounds were marked both by obstetrical complications and social stresses associated with poverty were twice as likely to be criminal offenders by ages 20 to 22 as those in either the biological or social risk groups. (Data from Raine et al., 1996.)

RETRIEVAL PRACTICE

- How do biological and psychological factors contribute to antisocial personality disorder?

ANSWER: Twin and adoption studies show that biological relatives of people with this disorder are at increased risk for antisocial behavior. Negative environmental factors, such as poverty or childhood abuse, may channel genetic traits such as fearlessness in more dangerous directions—toward aggression and away from social responsibility.

Eating Disorders

15-21 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

Our bodies are naturally disposed to maintain a steady weight, including stored energy reserves for times when food becomes unavailable. But sometimes psychological influences overwhelm biological wisdom. This becomes painfully clear in three eating disorders.

- **Anorexia nervosa** typically begins as a weight-loss diet. People with anorexia—usually adolescents and 9 out of 10 times females—drop significantly below normal weight. Yet they feel fat, fear being fat, remain obsessed with losing weight, and sometimes exercise excessively. About half of those with anorexia display a binge-purge-depression cycle.
- **Bulimia nervosa** may also be triggered by a weight-loss diet, broken by gorging on forbidden foods. Binge-purge eaters—mostly women in their late teens or early twenties—eat in spurts, sometimes influenced by negative emotion or by friends who are bingeing (Crandall, 1988; Haedt-Matt & Keel, 2011). In a cycle of repeating episodes, overeating is followed by compensatory purging (through vomiting or laxative use), fasting, or excessive

© Nick Holt Photography

anorexia nervosa an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly underweight; sometimes accompanied by excessive exercise.

bulimia nervosa an eating disorder in which a person alternates binge eating (usually of high-calorie foods) with purging (by vomiting or laxative use) or fasting.

Sibling rivalry gone awry Twins Maria and Katy Campbell have anorexia nervosa. As children they competed to see who could be thinner. Now, says Maria, her anorexia nervosa is “like a ball and chain around my ankle that I can’t throw off” (Foster, 2011).

binge-eating disorder significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory purging or fasting that marks bulimia nervosa.

A too-fat body image underlies anorexia.

“Why do women have such low self-esteem? There are many complex psychological and societal reasons, by which I mean Barbie.”

Dave Barry, 1999

exercise (Wonderlich et al., 2007). Preoccupied with food (craving sweet and high-fat foods), and fearful of becoming overweight, binge-purge eaters experience bouts of depression, guilt, and anxiety during and following binges (Hinz & Williamson, 1987; Johnson et al., 2002). Unlike anorexia, bulimia is marked by weight fluctuations within or above normal ranges, making the condition easy to hide.

- Those with **binge-eating disorder** engage in significant bouts of overeating, followed by remorse. But they do not purge, fast, or exercise excessively and thus may be overweight.

A U.S. National Institute of Mental Health-funded study reported that, at some point during their lifetime, 0.6 percent of the Americans studied had met the criteria for anorexia, 1 percent for bulimia, and 2.8 percent for binge-eating disorder (Hudson et al., 2007). So, how can we explain these disorders?

Understanding Eating Disorders

Eating disorders do *not* provide (as some have speculated) a telltale sign of childhood sexual abuse (Smolak & Murnen, 2002; Stice, 2002). The family environment may provide a fertile ground for the growth of eating disorders in other ways, however.

- Mothers of girls with eating disorders tend to focus on their own weight and on their daughters’ weight and appearance (Pike & Rodin, 1991).
- Families of those with bulimia tend to have a higher-than-usual incidence of childhood obesity and negative self-evaluation (Jacobi et al., 2004).
- Families of those with anorexia tend to be competitive, high-achieving, and protective (Berg et al., 2014; Pate et al., 1992; Yates, 1989, 1990).

Those with eating disorders often have low self-evaluations, set perfectionist standards, fret about falling short of expectations, and are intensely concerned with how others perceive them (Brauhardt et al., 2014; Pieters et al., 2007; Polivy & Herman, 2002; Sherry & Hall, 2009). Some of these factors also predict teen boys’ pursuit of unrealistic muscularity (Ricciardelli & McCabe, 2004).

Hereditry also matters. Identical twins share these disorders more often than fraternal twins do (Culbert et al., 2009; Klump et al., 2009; Root et al., 2010). Scientists are now searching for culprit genes, which may influence the body’s available serotonin and estrogen (Klump & Culbert, 2007). In one analysis of 15 studies, having a gene that reduced available serotonin added 30 percent to a person’s risk of anorexia or bulimia (Calati et al., 2011).

But these disorders also have cultural and gender components. Ideal shapes vary across culture and time. In impoverished areas of the world, including much of Africa—where plumpness means prosperity and thinness can signal poverty or illness—bigger seems better (Knickmeyer, 2001; Swami et al., 2010). Bigger does not seem better in Western cultures, where, according to 222 studies of 141,000 people, the rise in eating disorders in the last half of the twentieth century coincided with a dramatic increase in women having a poor body image (Feingold & Mazzella, 1998).

Those most vulnerable to eating disorders are also those (usually women or gay men) who most idealize thinness and have the greatest body dissatisfaction (Feldman & Meyer, 2010; Kane, 2010; Stice et al., 2010). Should it surprise us, then, that when women view real and doctored images of unnaturally thin models and celebrities, they often feel ashamed, depressed, and dissatisfied with their own bodies—the very attitudes that predispose eating disorders (Grabe et al., 2008; Myers & Crowther, 2009; Tiggeman & Miller, 2010)? Eric Stice and his colleagues (2001) tested this modeling idea by giving some adolescent girls (but not others) a 15-month subscription to an American teen-fashion magazine. Compared with those who had not received the

magazine, vulnerable girls—defined as those who were already dissatisfied, idealizing thinness, and lacking social support—exhibited increased body dissatisfaction and eating disorder tendencies. Even ultra-thin models do not reflect the impossible standard of the classic Barbie doll, who had, when adjusted to a height of 5 feet 7 inches, a 32–16–29 figure (in centimeters, 82–41–73) (Norton et al., 1996).

There is, however, more to body dissatisfaction and anorexia than media effects (Ferguson et al., 2011). Peer influences, such as teasing, also matter. So does affluence, increased marriage age, and especially, competition for available mates.

Nevertheless, the sickness of today's eating disorders stems in part from today's weight-obsessed culture—a culture that says, in countless ways, “Fat is bad,” that motivates millions of women to be “always dieting,” and that encourages eating binges by pressuring women to live in a constant state of semistarvation. One former model told the story of how her anorexia caused her organs to fail (Caroll, 2013). Starving from not having eaten for days, she walked into a meeting with her modeling agent, who greeted her by saying, “Whatever you are doing, keep doing it.”

If cultural learning contributes to eating behavior, then might prevention programs increase acceptance of one's body? Reviews of prevention studies answer *Yes*. They seem especially effective if the programs are interactive and focused on girls over age 15 (Beintner et al., 2012; Stice et al., 2007; Vocks et al., 2010).

* * *

A growing number of people, especially teenagers and young adults are being diagnosed with psychological disorders. Although mindful of their pain, we can also be encouraged by their successes.

Many live satisfying lives. Some pursue brilliant careers, as did 18 U.S. presidents, including the periodically depressed Abraham Lincoln, according to one psychiatric analysis of their biographies (Davidson et al., 2006). The bewilderment, fear, and sorrow caused by psychological disorders are real. But, as this text's discussion of therapy shows, hope, too, is real.

Too thin? Many worry that such super-thin models make self-starvation seem fashionable.

RETRIEVAL PRACTICE

- People with _____ (anorexia nervosa/bulimia nervosa) continue to want to lose weight even when they are underweight. Those with _____ (anorexia nervosa/bulimia nervosa) tend to have weight that fluctuates within or above normal ranges.

ANSWERS: anorexia nervosa; bulimia nervosa

REVIEW Dissociative, Personality, and Eating Disorders

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

15-19 What are dissociative disorders, and why are they controversial?

15-20 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

15-21 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

Use  **LearningCurve** to create your personalized study plan, which will direct you to the resources that will help you most in  **LaunchPad**.

TERMS AND CONCEPTS TO REMEMBER

RETRIEVAL PRACTICE Test yourself on these terms by trying to write down the definition before flipping back to check your answers.

- dissociative disorders, p. 646
- dissociative identity disorder (DID), p. 647
- personality disorders, p. 649
- antisocial personality disorder, p. 649
- anorexia nervosa, p. 651
- bulimia nervosa, p. 651
- binge-eating disorder, p. 652

TEST YOURSELF

PSYCHOLOGICAL DISORDERS

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Introduction to Psychological Disorders

1. Two disorders are found worldwide. One is schizophrenia, and the other is _____.
2. Anna is embarrassed that it takes her several minutes to parallel park her car. She usually gets out of the car once or twice to inspect her distance both from the curb and from the nearby cars. Should she worry about having a psychological disorder?
3. What is *susto*, and is this a culture-specific or universal psychological disorder?
4. A therapist says that psychological disorders are sicknesses and people with these disorders should be treated as patients in a hospital. This therapist believes in the _____ model.
5. Many psychologists reject the "disorders-as-illness" view and instead contend that other factors may also be involved—for example, the person's bad habits and poor social skills. This view represents the _____ approach.
 - a. medical
 - b. evil spirits
 - c. biopsychosocial
 - d. diagnostic labels

6. Why is the DSM, and the DSM-5 in particular, considered controversial?
7. One predictor of psychiatric disorders that crosses ethnic and gender lines is _____.
8. The symptoms of _____ appear around age 10; _____ tend[s] to appear later, around age 25.
 - a. schizophrenia; bipolar disorder
 - b. bipolar disorder; schizophrenia
 - c. major depressive disorder; phobias
 - d. phobias; major depressive disorder

Anxiety Disorders, OCD, and PTSD

9. Anxiety that takes the form of an irrational and maladaptive fear of a specific object, activity, or situation is called a _____.
10. An episode of intense dread, accompanied by trembling, dizziness, chest pains, or choking sensations and by feelings of terror, is called
 - a. a specific phobia.
 - b. compulsion.
 - c. a panic attack.
 - d. an obsessive fear.
11. Marina became consumed with the need to clean the entire house and refused to participate in any other activities. Her family consulted a therapist, who diagnosed her as having _____ - _____ disorder.

12. The learning perspective proposes that phobias are
- a. the result of individual genetic makeup.
 - b. a way of repressing unacceptable impulses.
 - c. conditioned fears.
 - d. a symptom of having been abused as a child.

Depressive Disorders and Bipolar Disorder

13. The “gender gap” in depression refers to the finding that _____ risk of depression is nearly double that of _____.
14. Rates of bipolar disorder have risen dramatically in the twenty-first century, especially among
- a. middle-aged women.
 - b. middle-aged men.
 - c. females 19 and under.
 - d. males 19 and under.
15. Treatment for depression often includes drugs that increase supplies of the neurotransmitters _____ and _____.
16. Psychologists who emphasize the importance of negative perceptions, beliefs, and thoughts in depression are working within the _____ - _____ perspective.

Schizophrenia

17. Victor exclaimed, “The weather has been so schizophrenic lately: It’s hot one day and freezing the next!” Is this an accurate comparison? Why or why not?
18. A person with positive symptoms of schizophrenia is most likely to experience
- a. catatonia.
 - b. delusions.
 - c. withdrawal.
 - d. flat emotion.
19. People with schizophrenia may hear voices urging self-destruction, an example of a(n) _____.

20. Chances for recovery from schizophrenia are best when
- a. onset is sudden, in response to stress.
 - b. deterioration occurs gradually, during childhood.
 - c. no environmental causes can be identified.
 - d. there is a detectable brain abnormality.

Dissociative, Personality, and Eating Disorders

21. Dissociative identity disorder is controversial because
- a. dissociation is actually quite rare.
 - b. it was reported frequently in the 1920s but rarely today.
 - c. it is almost never reported outside North America.
 - d. its symptoms are nearly identical to those of obsessive-compulsive disorder.
22. A personality disorder, such as antisocial personality, is characterized by
- a. depression.
 - b. hallucinations.
 - c. inflexible and enduring behavior patterns that impair social functioning.
 - d. an elevated level of autonomic nervous system arousal.
23. PET scans of murderers’ brains have revealed
- a. higher-than-normal activation in the frontal lobes.
 - b. lower-than-normal activation in the frontal lobes.
 - c. more frontal lobe tissue than normal.
 - d. no differences in brain structures or activity.
24. Which of the following statements is true of bulimia nervosa?
- a. People with bulimia continue to want to lose weight even when they are underweight.
 - b. Bulimia is marked by weight fluctuations within or above normal ranges.
 - c. Bulimia patients often come from middle-class families that are competitive, high-achieving, and protective.
 - d. If one twin is diagnosed with bulimia, the chances of the other twin’s sharing the disorder are greater if they are fraternal rather than identical twins.

Find answers to these questions in Appendix D, in the back of the book.

Introduction to Therapy and the Psychological Therapies

Evaluating Psychotherapies

Biomedical Therapies and Preventing Psychological Disorders

THERAPY

.....

Kay Redfield Jamison, an award-winning clinical psychologist and world expert on the emotional extremes of bipolar disorder, knows her subject firsthand. “For as long as I can remember,” she recalled in *An Unquiet Mind*, “I was frighteningly, although often wonderfully, beholden to moods. Intensely emotional as a child, mercurial as a young girl, first severely depressed as an adolescent, and then unrelentingly caught up in the cycles of manic-depressive illness [now known as bipolar disorder] by the time I began my professional life, I became, both by necessity and intellectual inclination, a student of moods” (1995, pp. 4–5). Her life was blessed with times of intense sensitivity and passionate energy. But like her father’s, it was also at times plagued by reckless spending, racing conversation, and sleeplessness, alternating with swings into “the blackest caves of the mind.”

Then, “in the midst of utter confusion,” she made a sane and profoundly helpful decision. Risking professional embarrassment she made an appointment with a therapist, a psychiatrist she would visit weekly for years to come.

He kept me alive a thousand times over. He saw me through madness, despair, wonderful and terrible love affairs, disillusionments and triumphs, recurrences of illness, an almost fatal suicide attempt, the death of a man I greatly loved, and the enormous pleasures and aggravations of my professional life. . . . He was very tough, as well as very kind, and even though he understood more than anyone how much I felt I was losing—in energy, vivacity, and originality—by taking medication, he never was seduced into losing sight of the overall perspective of how costly, damaging, and life threatening my illness was. . . . Although I went to him to be treated for an illness, he taught me . . . the total beholdenness of brain to mind and mind to brain (pp. 87–88).

“Psychotherapy heals,” Jamison reports. “It makes some sense of the confusion, reins in the terrifying thoughts and feelings, returns some control and hope and possibility from it all.”

We will begin by exploring and evaluating *psychotherapies*, and then focus on *biomedical therapies*.

Dorothea Dix “I . . . call your attention to the state of the Insane Persons confined within this Commonwealth, in cages.”

Introduction to Therapy and the Psychological Therapies

THE LONG HISTORY OF EFFORTS to treat psychological disorders has included a bewildering mix of harsh and gentle methods. Well-meaning individuals have cut holes in people’s heads and restrained, bled, or “beat the devil” out of them. But they also have given warm baths and massages and placed people in sunny, serene environments. They have administered drugs. And they have talked with their patients about childhood experiences, current feelings, and maladaptive thoughts and behaviors.

Treating Psychological Disorders

16-1 How do *psychotherapy* and the *biomedical therapies* differ?

Reformers Philippe Pinel (1745–1826) and Dorothea Dix (1802–1887) pushed for gentler, more humane treatments and for constructing mental hospitals. Since the 1950s, the introduction of effective drug therapies and community-based treatment programs have emptied most of those hospitals.

Modern Western therapies can be classified into two main categories:

- In **psychotherapy**, a trained therapist uses psychological techniques to assist someone seeking to overcome difficulties or achieve personal growth. The therapist may seek to uncover hidden meaning from a client’s early relationships, to encourage the client to adopt new ways of thinking, or to replace old behaviors with new ones.
- **Biomedical therapy** offers medications and other biological treatments. For example, a person with severe depression, as we will see, may receive antidepressants, electroconvulsive shock therapy (ECT), or deep-brain stimulation.

Some psychologists consider psychotherapy to be a biological treatment, because changing the way we think and behave can prompt physical changes in the brain (Kandel, 2013). Effective psychotherapy is a brain-changing experience.

The care provider’s training and expertise, as well as the disorder itself, influence the choice of treatment. Psychotherapy and medication are often combined. Kay Redfield Jamison received psychotherapy in her meetings with her psychiatrist, and she took medications to control her wild mood swings.

Let’s look first at the psychotherapy options for those treated with “talk therapies.” Each is built on one or more of psychology’s major theories: psychodynamic, humanistic, behavioral, and cognitive. Most of these techniques can be used one-on-one or in groups. Some therapists combine techniques. And like Jamison, many patients also receive psychotherapy combined with medication. Many psychotherapists describe themselves as taking an **eclectic approach**, using a blend of psychotherapies.

The Granger Collection, NYC — All rights reserved.

The history of treatment Visitors to eighteenth-century mental hospitals paid to gawk at patients, as though they were viewing zoo animals. William Hogarth’s (1697–1764) painting captured one of these visits to London’s St. Mary of Bethlehem hospital (commonly called Bedlam).

Psychoanalysis and Psychodynamic Therapies

16-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

The first major psychological therapy was Sigmund Freud’s **psychoanalysis**. Although few clinicians today practice therapy as Freud did, his work deserves discussion. It helped form the foundation for treating psychological disorders, partly by influencing modern therapists working from the *psychodynamic* perspective.

Goals

Freud believed that in therapy, people could achieve healthier, less anxious living by releasing the energy they had previously devoted to id-ego-superego conflicts (Chapter 14). Freud assumed that we do not fully know ourselves. There are threatening things that we seem to want not to know—that we disavow or deny. “We can have loving feelings and hateful feelings toward the same person,” notes Jonathan Shedler (2009), and “we can desire something and also fear it.” Psychoanalysis was Freud’s method of helping people to face such unwelcome facts.

Freud’s therapy aimed to bring patients’ repressed or disowned feelings into conscious awareness. By helping them reclaim their unconscious thoughts and feelings, and by giving them *insight* into the origins of their disorders, he aimed to help them reduce growth-impeding inner conflicts.

Techniques

Psychoanalysis is historical reconstruction. Psychoanalytic theory emphasizes the power of childhood experiences to mold the adult. Thus, it aims to unearth one’s past in the hope of unmasking the present. After discarding hypnosis as an unreliable excavator, Freud turned to *free association*.

Imagine yourself as a patient using free association. You begin by relaxing, perhaps by lying on a couch. As the psychoanalyst sits out of your line of vision, you say aloud whatever comes to mind. At one moment, you’re relating a childhood memory. At another, you’re describing a dream or recent experience. It sounds easy, but soon you notice how often you edit your thoughts as you speak. You pause for a second before uttering an embarrassing thought. You omit what seems trivial, irrelevant, or shameful. Sometimes your mind goes blank or you find yourself unable to remember important details. You may joke or change the subject to something less threatening.

To the analyst, these mental blocks indicate **resistance**. They hint that anxiety lurks and you are defending against sensitive material. The analyst will note your resistances and then provide insight into their meaning. If offered at the right moment, this **interpretation**—of, say, your not wanting to talk about your mother—may illuminate the underlying wishes, feelings, and conflicts you are avoiding. The analyst may also offer an explanation of how this resistance fits with other pieces of your psychological puzzle, including those based on analysis of your dream content.

Over many such sessions, your relationship patterns surface in your interaction with your therapist. You may find yourself experiencing strong positive or negative feelings for your analyst. The analyst may suggest you are **transferring** feelings, such as feelings of dependency or mingled love and anger, that you experienced in earlier relationships with family members or other important people. By exposing such feelings, you may gain insight into your current relationships.

Relatively few North American therapists now offer traditional psychoanalysis. Much of its underlying theory is not supported by scientific research (Chapter 14). Analysts’ interpretations cannot be proven or disproven. And psychoanalysis takes considerable time and money, often years of several sessions per week. Some of these problems have been addressed in the modern psychodynamic perspective that has evolved from psychoanalysis.

RETRIEVAL PRACTICE

- In psychoanalysis, when patients experience strong feelings for their therapist, this is called _____. Patients are said to demonstrate anxiety when they put up mental blocks around sensitive memories, indicating _____. The therapist will attempt to provide insight into the underlying anxiety by offering a(n) _____ of the mental blocks.

psychotherapy treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth.

biomedical therapy prescribed medications or procedures that act directly on the person’s physiology.

eclectic approach an approach to psychotherapy that uses techniques from various forms of therapy.

psychoanalysis Sigmund Freud’s therapeutic technique. Freud believed the patient’s free associations, resistances, dreams, and transferences—and the therapist’s interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight.

resistance in psychoanalysis, the blocking from consciousness of anxiety-laden material.

interpretation in psychoanalysis, the analyst’s noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight.

transference in psychoanalysis, the patient’s transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent).

“I haven’t seen my analyst in 200 years. He was a strict Freudian. If I’d been going all this time, I’d probably almost be cured by now.”

Woody Allen, after awakening from suspended animation in the movie *Sleeper*

psychodynamic therapy therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to enhance self-insight.

Psychodynamic Therapy

Although influenced by Freud's ideas, **psychodynamic therapists** don't talk much about id, ego, and superego. Instead they try to help people understand their current symptoms. They focus on themes across important relationships, including childhood experiences and the therapist relationship. Rather than lying on a couch, out of the therapist's line of vision, patients meet with their therapist face-to-face. These sessions take place once or twice a week (rather than several times per week), and often for only a few weeks or months.

In these sessions, patients gain perspective by exploring defended-against thoughts and feelings. Therapist David Shapiro (1999, p. 8) illustrates this with the case of a young man who had told women that he loved them, when he knew that he didn't. His explanation: They expected it, so he said it. But with his wife, who wishes he would say that he loves her, he finds he "cannot" do that—"I don't know why, but I can't."

Therapist: Do you mean, then, that if you could, you would like to?

Patient: Well, I don't know. . . . Maybe I can't say it because I'm not sure it's true. Maybe I don't love her.

Further interactions reveal that he can't express real love because it would feel "mushy" and "soft" and therefore unmanly. He is "in conflict with himself, and he is cut off from the nature of that conflict." Shapiro noted that with such patients, who are estranged from themselves, therapists using psychodynamic techniques "are in a position to introduce them to themselves. We can restore their awareness of their own wishes and feelings, and their awareness, as well, of their reactions against those wishes and feelings."

Psychodynamic therapists may also help reveal past relationship troubles as the origin of current difficulties. Jonathan Shedler (2010a) recalls his patient Jeffrey's complaints of difficulty getting along with his colleagues and wife, who saw him as hypercritical. Jeffrey then "began responding to me as if I were an unpredictable, angry adversary." Shedler seized this opportunity to help Jeffrey recognize the relationship pattern, and its roots in the attacks and humiliation he experienced from his alcohol-abusing father—and to work through and let go of this defensive responding to people.

Interpersonal psychotherapy, a brief (12- to 16-session) variation of psychodynamic therapy, has effectively treated depression (Cuijpers, 2011; Markowitz & Weissman, 2012). Although interpersonal psychotherapy aims to help people gain insight into the roots of their difficulties, its goal is symptom relief in the here and now. Rather than focusing mostly on undoing past hurts and offering interpretations, the therapist concentrates primarily on current relationships and on helping people improve their relationship skills.

Face-to-face therapy In this type of therapy session, the couch has disappeared. But the influence of psychoanalytic theory may not have, especially if the therapist seeks information about the patient's childhood and helps the patient reclaim unconscious feelings.

Tetra Images/Getty Images

The case of Anna, a 34-year-old married professional, illustrates these goals. Five months after receiving a promotion, with accompanying increased responsibilities and longer hours, Anna experienced tensions with her husband over his wish for a second child. She began feeling depressed, had trouble sleeping, became irritable, and was gaining weight. A typical psychodynamic therapist might have helped Anna gain insight into her angry impulses and her defenses against anger. An interpersonal therapist would do the same, but would also engage her thinking on more immediate issues—how she could balance work and home, resolve the dispute with her husband, and express her emotions more effectively (Markowitz et al., 1998).

Humanistic Therapies

16-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?

The *humanistic* perspective (Chapter 14) emphasizes people's inherent potential for self-fulfillment. Like psychodynamic therapies, humanistic therapies have attempted to reduce growth-impeding inner conflicts by providing clients with new insights. Indeed, the psychodynamic and humanistic therapies are often referred to as **insight therapies**. But humanistic therapies differ from psychoanalytic therapies in many other ways:

- *Humanistic therapists aim to boost people's self-fulfillment by helping them grow in self-awareness and self-acceptance.*
- *Promoting this growth, not curing illness, is the therapy focus.* Thus, those in therapy became "clients" or just "persons" rather than "patients" (a change many other therapists have adopted).
- *The path to growth is taking immediate responsibility for one's feelings and actions, rather than uncovering hidden determinants.*
- *Conscious thoughts are more important than the unconscious.*
- *The present and future are more important than the past.* The goal is to explore feelings as they occur, rather than achieve insights into the childhood origins of the feelings.

Carl Rogers (1902–1987) developed the widely used humanistic technique he called **client-centered therapy**, which focuses on the person's conscious self-perceptions. In this *nondirective therapy*, the therapist listens, without judging or interpreting, and seeks to refrain from directing the client toward certain insights.

Believing that most people possess the resources for growth, Rogers (1961, 1980) encouraged therapists to exhibit *genuineness*, *acceptance*, and *empathy*. When therapists drop their facades and genuinely express their true feelings, when they enable their clients to feel unconditionally accepted, and when they empathically sense and reflect their clients' feelings, the clients may deepen their self-understanding and self-acceptance (Hill & Nakayama, 2000). As Rogers (1980, p. 10) explained,

Hearing has consequences. When I truly hear a person and the meanings that are important to him at that moment, hearing not simply his words, but him, and when I let him know that I have heard his own private personal meanings, many things happen. There is first of all a grateful look. He feels released. He wants to tell me more about his world. He surges forth in a new sense of freedom. He becomes more open to the process of change.

I have often noticed that the more deeply I hear the meanings of the person, the more there is that happens. Almost always, when a person realizes he has been deeply heard, his eyes moisten. I think in some real sense he is weeping for joy. It is as though he were saying, "Thank God, somebody heard me. Someone knows what it's like to be me."

"Hearing" refers to Rogers' technique of **active listening**—echoing, restating, and seeking clarification of what the person expresses (verbally or nonverbally) and acknowledging the expressed feelings. Active listening is now an accepted part of therapeutic counseling practices in many schools, colleges, and clinics. The counselor listens attentively and interrupts only to restate and confirm feelings, to accept what is being expressed, or to seek clarification. The following brief excerpt between Rogers and a male client illustrates how he sought to provide a psychological mirror that would help clients see themselves more clearly.

Rogers: Feeling that now, hm? That you're just no good to yourself, no good to anybody. Never will be any good to anybody. Just that you're completely worthless, huh?—Those really are lousy feelings. Just feel that you're no good at all, hm?

insight therapies a variety of therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses.

client-centered therapy a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as active listening within a genuine, accepting, empathic environment to facilitate clients' growth. (Also called *person-centered therapy*.)

active listening empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers' client-centered therapy.

"We have two ears and one mouth that we may listen the more and talk the less."

Zeno, 335–263 B.C.E., *Diogenes Laertius*

unconditional positive regard

a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients develop self-awareness and self-acceptance.

Client: Yeah. (*Muttering in low, discouraged voice*) That's what this guy I went to town with just the other day told me.

Rogers: This guy that you went to town with really told you that you were no good? Is that what you're saying? Did I get that right?

Client: M-hm.

Rogers: I guess the meaning of that if I get it right is that here's somebody that—meant something to you and what does he think of you? Why, he's told you that he thinks you're no good at all. And that just really knocks the props out from under you. (*Client weeps quietly.*) It just brings the tears. (*Silence of 20 seconds*)

Client: (*Rather defiantly*) I don't care though.

Rogers: You tell yourself you don't care at all, but somehow I guess some part of you cares because some part of you weeps over it.

(Meador & Rogers, 1984, p. 167)

Can a therapist be a perfect mirror, without selecting and interpreting what is reflected? Rogers conceded that one cannot be *totally* nondirective. Nevertheless, he believed that the therapist's most important contribution is to accept and understand the client. Given a nonjudgmental, grace-filled environment that provides **unconditional positive regard**, people may accept even their worst traits and feel valued and whole.

If you want to listen more actively in your own relationships, three Rogers-inspired hints may help:

1. **Paraphrase.** Rather than saying "I know how you feel," check your understandings by summarizing the person's words in your own words.
2. **Invite clarification.** "What might be an example of that?" may encourage the person to say more.
3. **Reflect feelings.** "It sounds frustrating" might mirror what you're sensing from the person's body language and intensity.

Active listening Carl Rogers (right) empathized with a client during this group therapy session.

Behavior Therapies

16-4 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

The insight therapies assume that many psychological problems diminish as self-awareness grows. Psychodynamic therapists expect problems to subside as people gain insight into their unresolved and unconscious tensions. Humanistic therapists expect

problems to diminish as people get in touch with their feelings. Proponents of **behavior therapies**, however, doubt the healing power of self-awareness. (You can become aware of why you are highly anxious during exams and still be anxious.) They assume that problem behaviors *are* the problems, and the application of learning principles can eliminate them. Rather than delving deeply below the surface looking for inner causes, behavior therapists view maladaptive symptoms—such as phobias or sexual dysfunctions—as learned behaviors that can be replaced by constructive behaviors.

Classical Conditioning Techniques

One cluster of behavior therapies derives from principles developed in Ivan Pavlov's early twentieth-century conditioning experiments (Chapter 7). As Pavlov and others showed, we learn various behaviors and emotions through classical conditioning. Could maladaptive symptoms be examples of conditioned responses? If so, might reconditioning be a solution? Learning theorist O. H. Mowrer thought so and developed a successful conditioning therapy for chronic bed-wetters. The child sleeps on a liquid-sensitive pad connected to an alarm. Moisture on the pad triggers the alarm, waking the child. With sufficient repetition, this association of bladder relaxation with waking up stops the bed-wetting. In three out of four cases the treatment is effective, and the success provides a boost to the child's self-image (Christophersen & Edwards, 1992; Houts et al., 1994).

Another example: If a claustrophobic fear of elevators is a learned aversion to being in a confined space, then might one unlearn that association by reconditioning to replace the fear response? **Counterconditioning** pairs the trigger stimulus (in this case, the enclosed space of the elevator) with a new response (relaxation) that is incompatible with fear. Two specific counterconditioning techniques—*exposure therapy* and *aversive conditioning*—have successfully counterconditioned people with such fears.

RETRIEVAL PRACTICE

- What might a psychodynamic therapist say about Mowrer's therapy for bed-wetting? How might a behavior therapist reply?

ANSWER: A psychodynamic therapist might be more interested in helping the child develop insight about the underlying problems that have caused the bed-wetting response. A behavior therapist would be more likely to agree with Mowrer that the bed-wetting symptom is the problem, and that counterconditioning the unwanted behavior would indeed bring emotional relief.

Exposure Therapies Picture this scene reported in 1924 by behaviorist psychologist Mary Cover Jones: Three-year-old Peter is petrified of rabbits and other furry objects. Jones plans to replace Peter's fear of rabbits with a conditioned response incompatible with fear. Her strategy is to associate the fear-evoking rabbit with the pleasurable, relaxed response associated with eating.

Kim Reinick/ Shutterstock
Creativ Studio Heinemann/Getty Images

As Peter begins his midafternoon snack, Jones introduces a caged rabbit on the other side of the huge room. Peter, eagerly munching away on his crackers and drinking his milk, hardly notices. On succeeding days, she gradually moves the rabbit closer and closer. Within two months, Peter is tolerating the rabbit in his lap, even stroking it while he eats. Moreover, his fear of other furry objects subsides as well, having been *countered*, or replaced, by a relaxed state that cannot coexist with fear (Fisher, 1984; Jones, 1924).

Unfortunately for those who might have been helped by her counterconditioning procedures, Jones' story of Peter and the rabbit did not immediately become part of psychology's

behavior therapy therapy that applies learning principles to the elimination of unwanted behaviors.

counterconditioning behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*.

exposure therapies behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imagination or actual situations) to the things they fear and avoid.

systematic desensitization a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias.

virtual reality exposure therapy an anxiety treatment that progressively exposes people to electronic simulations of their greatest fears, such as airplane flying, spiders, or public speaking.

lore. It was more than 30 years later that psychiatrist Joseph Wolpe (1958; Wolpe & Plaud, 1997) refined Jones' technique into what are now the most widely used types of behavior therapies: **exposure therapies**, which expose people to what they normally avoid or escape (behaviors that get reinforced by reduced anxiety). Exposure therapies have them face their fear, and thus overcome their fear of the fear response itself. As people can habituate to the sound of a train passing their new apartment, so, with repeated exposure, can they become less anxiously responsive to things that once petrified them (Barrera et al., 2013; Foa et al., 2013).

One widely used exposure therapy is **systematic desensitization**. Wolpe assumed, as did Jones, that you cannot be simultaneously anxious and relaxed. Therefore, if you can repeatedly relax when facing anxiety-provoking stimuli, you can gradually eliminate your anxiety. The trick is to proceed gradually. Imagine yourself afraid of public speaking. A behavior therapist might first ask for your help in constructing a hierarchy of anxiety-triggering speaking situations. Yours might range from mildly anxiety-provoking situations, perhaps speaking up in a small group of friends, to panic-provoking situations, such as having to address a large audience.

Next, using *progressive relaxation*, the therapist would train you to relax one muscle group after another, until you achieve a blissful state of complete relaxation and comfort. Then the therapist would ask you to imagine, with your eyes closed, a mildly anxiety-arousing situation: You are having coffee with a group of friends and are trying to decide whether to speak up. If imagining the scene causes you to feel any anxiety, you would signal your tension by raising your finger, and the therapist would instruct you to switch off the mental image and go back to deep relaxation. This imagined scene is repeatedly paired with relaxation until you feel no trace of anxiety.

The therapist would progress up the constructed anxiety hierarchy, using the relaxed state to desensitize you to each imagined situation. After several sessions, you move to actual situations and practice what you had only imagined before, beginning with relatively easy tasks and gradually moving to more anxiety-filled ones. Conquering your anxiety in an actual situation, not just in your imagination, raises your self-confidence (Foa & Kozak, 1986; Williams, 1987). Eventually, you may even become a confident public speaker. Often people fear not just a situation, such as public speaking, but also being incapacitated by their own fear response. As their fear subsides, so also does their fear of the fear.

When an anxiety-arousing situation is too expensive, difficult, or embarrassing to re-create, **virtual reality exposure therapy** offers an efficient middle ground. Wearing a head-mounted display unit that projects a three-dimensional virtual world, you would view a lifelike series of scenes that would be tailored to your particular fear and that

“The only thing we have to fear is fear itself.”

U.S. President Franklin D. Roosevelt First Inaugural Address, 1933

Virtual reality exposure therapy

Within the confines of a room, virtual reality technology exposes people to vivid simulations of feared stimuli, such as walking across a rickety bridge high off the ground.

Jack Keirse/Emory University

William Britten/E+/Getty Images

shift as your head turns. Experiments led by several research teams have treated many different people with many different fears—flying, heights, particular animals, and public speaking (Parsons & Rizzo, 2008). People who fear flying, for example, can peer out a virtual window of a simulated plane, feel vibrations, and hear the engine roar as the plane taxis down the runway and takes off. In studies comparing control groups with people experiencing virtual reality exposure therapy, the therapy has provided relief from real-life fear (Gonçalves et al., 2012; Opriș et al., 2012).

Aversive Conditioning In systematic desensitization, the goal is substituting a positive (relaxed) response for a negative (fearful) response to a *harmless* stimulus. In **aversive conditioning**, the goal is substituting a negative (aversive) response for a positive response to a *harmful* stimulus (such as alcohol). Thus, aversive conditioning is the reverse of systematic desensitization—it seeks to condition an aversion to something the person *should* avoid.

The procedure is simple: It associates the unwanted behavior with unpleasant feelings. To treat nail biting, one can paint the fingernails with a nasty-tasting nail polish (Baskind, 1997). To treat alcohol use disorder, an aversion therapist offers the client appealing drinks laced with a drug that produces severe nausea. By linking alcohol with violent nausea (recall the taste-aversion experiments with rats and coyotes in Chapter 7), the therapist seeks to transform the person's reaction to alcohol from positive to negative (FIGURE 16.1).

Does aversive conditioning work? In the short run it may. Arthur Wiens and Carol Menustik (1983) studied 685 hospital patients with alcohol use disorder who completed an aversion therapy program. One year later, after returning for several booster treatments of alcohol-sickness pairings, 63 percent were still successfully abstaining. But after three years, only 33 percent had remained abstinent.

The problem is that in therapy (as in research), cognition influences conditioning. People know that outside the therapist's office they can drink without fear of nausea. Their ability to discriminate between the aversive conditioning situation and all other situations can limit the treatment's effectiveness. Thus, therapists often use aversive conditioning in combination with other treatments.

Operant Conditioning

16-5 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

The work of B. F. Skinner and others teaches us a basic principle of operant conditioning: Voluntary behaviors are strongly influenced by their consequences. Knowing this, some behavior therapists practice *behavior modification*. They reinforce desired behaviors, and they withhold reinforcement for undesired behaviors. Using operant conditioning to solve specific behavior problems has raised hopes for some otherwise hopeless cases. Children with intellectual disabilities have been taught to care for themselves. Socially withdrawn children with autism spectrum disorder (ASD) have learned to interact. People with schizophrenia have been helped to behave more rationally in their hospital ward. In such cases, therapists use positive reinforcers to shape behavior in a step-by-step manner, rewarding closer and closer approximations of the desired behavior.

In extreme cases, treatment must be intensive. One study worked with 19 withdrawn, uncommunicative 3-year-olds with ASD. Each participated in a 2-year program in which their parents spent 40 hours a week attempting to shape their behavior

▼ FIGURE 16.1

Aversion therapy for alcohol use disorder After repeatedly imbibing an alcoholic drink mixed with a drug that produces severe nausea, some people with a history of alcohol use disorder develop at least a temporary conditioned aversion to alcohol. (Remember: US is unconditioned stimulus, UR is unconditioned response, NS is neutral stimulus, CS is conditioned stimulus, and CR is conditioned response.)

aversive conditioning a type of counterconditioning that associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol).

token economy an operant conditioning procedure in which people earn a token of some sort for exhibiting a desired behavior and can later exchange their tokens for various privileges or treats.

(Lovaas, 1987). The combination of positively reinforcing desired behaviors, and ignoring or punishing aggressive and self-abusive behaviors, worked wonders for some. By first grade, 9 of the 19 children were functioning successfully in school and exhibiting normal intelligence. In a group of 40 comparable children not undergoing this effortful treatment, only one showed similar improvement. (Ensuing studies focused on the effective aspect—positive reinforcement.)

Rewards used to modify behavior vary. For some people, the reinforcing power of attention or praise is sufficient. Others require concrete rewards, such as food. In institutional settings, therapists may create a **token economy**. When people display appropriate behavior, such as getting out of bed, washing, dressing, eating, talking coherently, cleaning up their rooms, or playing cooperatively, they receive a token or plastic coin as a positive reinforcer. Later, they can exchange their accumulated tokens for various rewards, such as candy, TV time, trips to town, or better living quarters. Token economies have been successfully applied in various settings (homes, classrooms, hospitals, institutions for juvenile offenders) and among members of various populations (including disturbed children and people with schizophrenia and other mental disabilities).

Critics of behavior modification express two concerns. The first is practical: *How durable are the behaviors?* Will people become so dependent on extrinsic rewards that the appropriate behaviors will stop when the reinforcers stop? Proponents of behavior modification believe the behaviors will endure if therapists wean patients from the tokens by shifting them toward other, real-life rewards, such as social approval. They also point out that the appropriate behaviors themselves can be intrinsically rewarding. For example, as a withdrawn person becomes more socially competent, the intrinsic satisfactions of social interaction may help the person maintain the behavior.

The second concern is ethical: *Is it right for one human to control another's behavior?* Those who set up token economies deprive people of something they desire and decide which behaviors to reinforce. To critics, this whole process has an authoritarian taint. Advocates reply that some patients request the therapy. Moreover, control already exists; rewards and punishers are already maintaining destructive behavior patterns. So why not reinforce adaptive behavior instead? Treatment with positive rewards is more humane than being institutionalized or punished, advocates argue, and the right to effective treatment and an improved life justifies temporary deprivation.

RETRIEVAL PRACTICE

- What are the *insight therapies*, and how do they differ from behavior therapies?
ANSWER: The *insight therapies*—psychodynamic and humanistic therapies—seek to relieve problems by providing an understanding of their origins. Behavior therapies assume the problem behavior is the problem and treat it directly, paying less attention to its origins.
- Some maladaptive behaviors are learned. What hope does this fact provide?
ANSWER: If a behavior can be learned, it can be *unlearned*, and replaced by other more adaptive responses.
- Exposure therapies and aversive conditioning are applications of _____ conditioning. Token economies are an application of _____ conditioning.
ANSWERS: classical; operant

Cognitive Therapies

16-6 What are the goals and techniques of cognitive therapy and of cognitive-behavioral therapy?

We have seen how behavior therapists treat specific fears and problem behaviors. But how do they deal with depressive disorders? Or with generalized anxiety, in which anxiety has no focus? Behavior therapists treating these less clearly defined psychological problems have had help from the same *cognitive revolution* that has profoundly changed other areas of psychology during the last half-century.

Cognitive therapy for eating disorders aided by journaling

Cognitive therapists guide people toward new ways of explaining their good and bad experiences. By recording positive events and how she has enabled them, this woman may become more mindful of her self-control and more optimistic.

The **cognitive therapies** assume that our thinking colors our feelings (FIGURE 16.2). Between an event and our response lies the mind. Self-blaming and overgeneralized explanations of bad events are often an integral part of the vicious cycle of depression. The depressed person interprets a suggestion as criticism, disagreement as dislike, praise as flattery, friendliness as pity. Ruminating on such thoughts sustains the negative thinking. If such thinking patterns can be learned, then surely they can be replaced. Cognitive therapies therefore teach people new, more constructive ways of thinking. If people are miserable, they can be helped to change their minds.

“Life does not consist mainly, or even largely, of facts and happenings. It consists mainly of the storm of thoughts that are forever blowing through one’s mind.”

Mark Twain, 1835–1910

▼ FIGURE 16.2

A cognitive perspective on psychological disorders

The person’s emotional reactions are produced not directly by the event but by the person’s thoughts in response to the event.

Aaron Beck’s Therapy for Depression

Cognitive therapist Aaron Beck believes that changing people’s thinking can change their functioning. When Beck analyzed depressed people’s dreams, he found recurring negative themes of loss, rejection, and abandonment that extended into their waking thoughts. Such negativity even extends into therapy, as clients recall and rehearse their failings and worst impulses (Kelly, 2000). With cognitive therapy, Beck and his colleagues (1979) sought to reverse clients’ *catastrophizing* beliefs about themselves, their situations, and their futures. Gentle questioning seeks to reveal irrational thinking, and then to persuade people to remove the dark glasses through which they view life (Beck et al., 1979, pp. 145–146):

Client: I agree with the descriptions of me but I guess I don’t agree that the way I think makes me depressed.

Beck: How do you understand it?

Client: I get depressed when things go wrong. Like when I fail a test.

Beck: How can failing a test make you depressed?

Client: Well, if I fail I’ll never get into law school.

cognitive therapy therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions.

Beck: So failing the test means a lot to you. But if failing a test could drive people into clinical depression, wouldn't you expect everyone who failed the test to have a depression? . . . Did everyone who failed get depressed enough to require treatment?

Client: No, but it depends on how important the test was to the person.

Beck: Right, and who decides the importance?

Client: I do.

Beck: And so, what we have to examine is your way of viewing the test (or the way that you think about the test) and how it affects your chances of getting into law school. Do you agree?

Client: Right.

Beck: Do you agree that the way you interpret the results of the test will affect you? You might feel depressed, you might have trouble sleeping, not feel like eating, and you might even wonder if you should drop out of the course.

Client: I have been thinking that I wasn't going to make it. Yes, I agree.

Beck: Now what did failing mean?

Client: (tearful) That I couldn't get into law school.

Beck: And what does that mean to you?

Client: That I'm just not smart enough.

Beck: Anything else?

Client: That I can never be happy.

Beck: And how do these thoughts make you feel?

Client: Very unhappy.

Beck: So it is the meaning of failing a test that makes you very unhappy. In fact, believing that you can never be happy is a powerful factor in producing unhappiness. So, you get yourself into a trap—by definition, failure to get into law school equals "I can never be happy."

We often think in words. Therefore, getting people to change what they say to themselves is an effective way to change their thinking. Perhaps you can identify with the anxious students who, before an exam, make matters worse with self-defeating thoughts: "This exam's probably going to be impossible. All these other students seem so relaxed and confident. I wish I were better prepared. Anyhow, I'm so nervous I'll forget everything." To change such negative self-talk, Donald Meichenbaum (1977, 1985) offered *stress inoculation training*: teaching people to restructure their thinking in stressful situations. Sometimes it may be enough simply to say more positive things to oneself: "Relax. The exam may be hard, but it will be hard for everyone else, too. I studied harder than most people. Besides, I don't need a perfect score to get a good grade." After being trained to dispute their negative thoughts, depression-prone children, teens, and college students exhibit a greatly reduced rate of future depression (Reivich et al., 2013; Seligman et al.,

PEANUTS

▼ **TABLE 16.1**
Selected Cognitive Therapy Techniques

Aim of Technique	Technique	Therapists' Directives
<i>Reveal beliefs</i>	Question your interpretations	Explore your beliefs, revealing faulty assumptions such as "I must be liked by everyone."
	Rank thoughts and emotions	Gain perspective by ranking your thoughts and emotions from mildly to extremely upsetting.
<i>Test beliefs</i>	Examine consequences	Explore difficult situations, assessing possible consequences and challenging faulty reasoning.
	Decatastrophize thinking	Work through the actual worst-case consequences of the situation you face (it is often not as bad as imagined). Then determine how to cope with the real situation you face.
<i>Change beliefs</i>	Take appropriate responsibility	Challenge total self-blame and negative thinking, noting aspects for which you may be truly responsible, as well as aspects that aren't your responsibility.
	Resist extremes	Develop new ways of thinking and feeling to replace maladaptive habits. For example, change from thinking "I am a total failure" to "I got a failing grade on that paper, and I can make these changes to succeed next time."

2009). To a large extent, it *is* the thought that counts. TABLE 16.1 provides a sampling of techniques commonly used in cognitive therapy.

It's not just depressed people who can benefit from positive self-talk. We all talk to ourselves ("Where did I leave the keys?" "I wish I hadn't said that"). The findings of nearly three dozen sport psychology studies show that self-talk interventions can enhance the learning of athletic skills (Hatzigeorgiadas et al., 2011). For example, novice basketball players may be trained to think "focus" and "follow through," swimmers to think "high elbow," and tennis players to think "look at the ball."

Cognitive-Behavioral Therapy

Cognitive-behavioral therapy (CBT), today's most widely practiced psychotherapy, aims not only to alter the way people think (cognitive therapy), but also to alter the way they act (behavior therapy). It seeks to make people aware of their irrational negative thinking, to replace it with new ways of thinking, and to *practice* the more positive approach in everyday settings. Behavioral change is typically addressed first, followed by sessions on cognitive change; the therapy concludes with a focus on maintaining both and preventing relapses.

Anxiety, depressive disorders, and bipolar disorder share a common problem: emotion regulation (Aldao & Nolen-Hoeksema, 2010). An effective CBT program for these emotional disorders trains people both to replace their catastrophizing thinking with more realistic appraisals, and, as homework, to practice behaviors that are incompatible with their problem (Kazantzis et al., 2010a,b; Moses & Barlow, 2006). A person might, for example, keep a log of daily situations associated with negative and positive emotions, and engage more in activities that lead them to feeling good. Or those who fear social situations might be assigned to practice approaching people.

CBT may also be useful with obsessive-compulsive disorder. In one study, people learned to prevent their compulsive behaviors by relabeling their obsessive thoughts (Schwartz et al., 1996). Feeling the urge to wash their hands again, they would tell themselves, "I'm having a compulsive urge," and attribute it to their brain's abnormal activity, as previously viewed in their PET scans. Instead of giving in to the urge, they would then spend 15 minutes in an enjoyable, alternative behavior, such as practicing an instrument, taking a walk, or gardening. This helped "unstuck" the brain by shifting

"The trouble with most therapy is that it helps you to feel better. But you don't get better. You have to back it up with action, action, action."

Therapist Albert Ellis (1913–2007)

cognitive-behavioral therapy (CBT) a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior).

attention and engaging other brain areas. For two or three months, the weekly therapy sessions continued, with relabeling and refocusing practice at home. By the study’s end, most participants’ symptoms had diminished and their PET scans revealed normalized brain activity. Many other studies confirm CBT’s effectiveness for treating anxiety, depression, and anorexia or bulimia nervosa (Covin et al., 2008; Zalta, 2011).

Studies have also found that cognitive-behavioral skills can be taught and therapy can be effectively conducted over the Internet (Andersson et al., 2012; Stross, 2011). To make psychological treatment more accessible and affordable, some mental health experts advocate phone-based interventions, web-based skill training, work-setting treatment, and self-help efforts facilitated by groups, books, and even phone apps (Kazdin & Blase, 2011a,b; Merry et al., 2012; Teachman, 2014). Skype therapy may lack eye contact, but it means “the therapist can see you now”—anywhere and anytime.

RETRIEVAL PRACTICE

- How do the humanistic and cognitive therapies differ?
ANSWER: By reflecting clients' feelings in a nondirective setting, the humanistic therapies attempt to foster personal growth by helping clients become more self-aware and self-accepting. By making clients aware of self-defeating patterns of thinking, cognitive therapies guide people toward more adaptive ways of thinking about themselves and their world.
- An influential cognitive therapy for depression was developed by _____.
ANSWER: Aaron Beck
- What is cognitive-behavioral therapy, and what sorts of problems does this therapy best address?
ANSWER: This integrative therapy helps people change self-defeating thinking and behavior. It has been shown to be effective for those with anxiety disorders, obsessive-compulsive disorder, depressive disorders, bipolar disorder, and eating disorders.

Group and Family Therapies

16-7 What are the aims and benefits of group and family therapies?

Group Therapy

Except for traditional psychoanalysis, most therapies may also occur in small groups. **Group therapy** does not provide the same degree of therapist involvement with each client. However, it offers many benefits:

- *It saves therapists’ time and clients’ money*, often with no less effectiveness than individual therapy (Fuhriman & Burlingame, 1994).
- *It offers a social laboratory for exploring social behaviors and developing social skills.* Therapists frequently suggest group therapy for people experiencing frequent conflicts or whose behavior distresses others. For up to 90 minutes weekly, the therapist guides people’s interactions as they discuss issues and try out new behaviors.
- *It enables people to see that others share their problems.* It can be a relief to discover that you are not alone—to learn that others, despite their composure, experience some of the same troublesome feelings and behaviors.
- *It provides feedback as clients try out new ways of behaving.* Hearing that you look poised, even though you feel anxious and self-conscious, can be very reassuring.

Family Therapy

One special type of group interaction, **family therapy**, assumes that no person is an island: We live and grow in relation to others, especially our families. We struggle to differentiate ourselves from our families, but we also need to connect with them emotionally. Some of our problem behaviors arise from the tension between these two tendencies, which can create family stress.

group therapy therapy conducted with groups rather than individuals, permitting therapeutic benefits from group interaction.

family therapy therapy that treats the family as a system. Views an individual’s unwanted behaviors as influenced by, or directed at, other family members.

Unlike most psychotherapy, which focuses on what happens inside the person's own skin, family therapists work with multiple family members to heal relationships and to mobilize family resources. They tend to view the family as a system in which each person's actions trigger reactions from others, and they help family members discover their role within their family's social system. A child's rebellion, for example, affects and is affected by other family tensions. Therapists also attempt—usually with some success, research suggests—to open up communication within the family or to help family members discover new ways of preventing or resolving conflicts (Hazelrigg et al., 1987; Shadish et al., 1993).

John Moore/Getty Images

Family therapy This type of therapy often acts as a preventive mental health strategy and may include marriage therapy, as shown here at a retreat for military families. The therapist helps family members understand how their ways of relating to one another create problems. The treatment's emphasis is not on changing the individuals but on changing their relationships and interactions.

Self-Help Groups

Many people also participate in self-help and support groups (Yalom, 1985). One analysis of online support groups and more than 14,000 self-help groups reported that most support groups focus on stigmatized or hard-to-discuss illnesses (Davison et al., 2000). AIDS patients, for example, are 250 times more likely than hypertension patients to be in support groups. Those struggling with anorexia and alcohol use disorder often join groups; those with migraines and ulcers usually do not. People with hearing loss have national organizations with local chapters; people with vision loss more often cope on their own.

The grandparent of support groups, Alcoholics Anonymous (AA), reports having 2.1 million members in 115,000 groups worldwide. Its famous 12-step program, emulated by many other self-help groups, asks members to admit their powerlessness, to seek help from a higher power and from one another, and (the twelfth step) to take the message to others in need of it. In one eight-year, \$27 million investigation, AA participants reduced their drinking sharply, although so did those assigned to cognitive-behavioral therapy or to an alternative therapy (Project Match, 1997). Other studies have similarly found that 12-step programs such as AA have helped reduce alcohol use disorder comparably to other treatment interventions (Ferri et al., 2006; Moos & Moos, 2005). Those whose personal stories include a “redemptive narrative”—who see something good as having come from their experience—more often sustain sobriety (Dunlop & Tracy, 2013). Also, the more meetings members attend, the greater their alcohol abstinence (Moos & Moos, 2006). In one study of 2300 veterans who sought treatment for alcohol use disorder, a high level of AA involvement was followed by diminished alcohol problems (McKellar et al., 2003).

In an individualistic age, with more and more people living alone or feeling isolated, the popularity of support groups—for the addicted, the bereaved, the divorced, or simply those seeking fellowship and growth—seems to reflect a longing for community and connectedness. More than 100 million Americans belong to small religious, interest, or self-help groups that meet regularly—and 9 in 10 report that group members “support each other emotionally” (Gallup, 1994).

* * *

For a synopsis of the modern forms of psychotherapy we've been discussing, see **TABLE 16.2** on the next page.

With more than 2 million members worldwide, AA is said to be “the largest organization on Earth that nobody wanted to join” (Finlay, 2000).

▼ **TABLE 16.2**
Comparing Modern Psychotherapies

Therapy	Presumed Problem	Therapy Aim	Therapy Technique
<i>Psychodynamic</i>	Unconscious conflicts from childhood experiences	Reduce anxiety through self-insight.	Interpret patients' memories and feelings.
<i>Client-centered</i>	Barriers to self-understanding and self-acceptance	Enable growth via unconditional positive regard, genuineness, acceptance, and empathy.	Listen actively and reflect clients' feelings.
<i>Behavior</i>	Dysfunctional behaviors	Learn adaptive behaviors; extinguish problem ones.	Use classical conditioning (via exposure or aversion therapy) or operant conditioning (as in token economies).
<i>Cognitive</i>	Negative, self-defeating thinking	Promote healthier thinking and self-talk.	Train people to dispute negative thoughts and attributions.
<i>Cognitive-behavioral</i>	Self-harmful thoughts and behaviors	Promote healthier thinking and adaptive behaviors.	Train people to counter self-harmful thoughts and to act out their new ways of thinking.
<i>Group and family</i>	Stressful relationships	Heal relationships.	Develop an understanding of family and other social systems, explore roles, and improve communication.

REVIEW Introduction to Therapy and the Psychological Therapies

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

- 16-1** How do *psychotherapy* and the *biomedical therapies* differ?
- 16-2** What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?
- 16-3** What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?
- 16-4** How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?
- 16-5** What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?
- 16-6** What are the goals and techniques of cognitive therapy and of cognitive-behavioral therapy?
- 16-7** What are the aims and benefits of group and family therapies?

Evaluating Psychotherapies

ADVICE COLUMNISTS FREQUENTLY URGE THEIR troubled letter writers to get professional help: “Seek counseling” or “Ask your mate to find a therapist.”

Many Americans share this confidence in psychotherapy’s effectiveness. Before 1950, psychiatrists were the primary providers of mental health care. Today’s providers include clinical and counseling psychologists, clinical social workers, clergy, marital and school counselors, and psychiatric nurses. With such an enormous outlay of time as well as money, effort, and hope, it is important to ask: Are the millions of people worldwide justified in placing their hopes in psychotherapy?

Is Psychotherapy Effective?

16-8 Does psychotherapy work? How can we know?

The question, though simply put, is not simple to answer. Measuring therapy’s effectiveness is not like taking your body’s temperature after a fever. So how can we assess psychotherapy’s effectiveness? By how we feel about our progress? By how our therapist feels about it? By how our friends and family feel about it? By how our behavior has changed?

Clients’ Perceptions

If clients’ testimonials were the only measuring stick, we could strongly affirm psychotherapy’s effectiveness. When 2900 *Consumer Reports* readers (1995; Kotkin et al., 1996; Seligman, 1995) related their experiences with mental health professionals, 89 percent said they were at least “fairly well satisfied.” Among those who recalled feeling *fair* or *very poor* when beginning therapy, 9 in 10 now were feeling *very good*, *good*, or at least *so-so*. We have their word for it—and who should know better?

We should not dismiss these testimonials. But for several reasons, client testimonials do not persuade psychotherapy’s skeptics:

- **People often enter therapy in crisis.** When, with the normal ebb and flow of events, the crisis passes, people may attribute their improvement to the therapy. Depressed people often get better no matter what they do.
- **Clients believe that treatment will be effective.** The *placebo effect* is the healing power of positive expectations.
- **Clients want to believe the therapy was worth the effort.** To admit investing time and money in something ineffective is like admitting to having one’s car serviced repeatedly by a mechanic who never fixes it. Self-justification is a powerful human motive, which helps explain why all therapies produce appreciative testimonials.
- **Clients generally speak kindly of their therapists.** Even if the problems remain, say the critics, clients “work hard to find something positive to say. The therapist had been very understanding, the client had gained a new perspective, he learned to communicate better, his mind was eased, anything at all so as not to have to say treatment was a failure” (Zilbergeld, 1983, p. 117).

As earlier chapters document, we are prone to selective and biased recall and to making judgments that confirm our beliefs. Consider the testimonials gathered in a massive experiment with over 500 Massachusetts boys, aged 5 to 13 years, many of whom seemed bound for delinquency. By the toss of a coin, half the boys were assigned to a 5-year treatment program. The treated boys were visited by counselors twice a month. They participated in community programs, and they received academic tutoring, medical attention, and family assistance as needed. Some 30 years later, Joan McCord (1978, 1979) located 485 participants, sent them questionnaires, and checked public records from courts, mental hospitals, and other sources. Was the treatment successful?

Jon Carter/Cartoonstock

Trauma: These women were mourning the tragic loss of lives and homes in the 2010 earthquake in China. Those who suffer through such trauma may benefit from counseling, though many people recover on their own or with the help of supportive relationships with family and friends. “Life itself still remains a very effective therapist,” noted psychodynamic therapist Karen Horney (*Our Inner Conflicts*, 1945).

Feng Li/Getty Images

Client testimonials were glowing. Some men noted that, had it not been for their counselors, “I would probably be in jail,” “My life would have gone the other way,” or “I think I would have ended up in a life of crime.” Court records offered apparent support: Even among the “difficult” boys in the treatment group, 66 percent had no official juvenile crime record.

But recall psychology’s most powerful tool for sorting reality from wishful thinking: the *control group*. For every boy in the treatment group, there was a similar boy in a control group, receiving no counseling. Of these untreated men, 70 percent had no juvenile record. On several other measures, such as a record of having committed a second crime, alcohol use disorder, death rate, and job satisfaction, the untreated men exhibited slightly *fewer* problems. The glowing testimonials of those treated had been unintentionally deceiving.

Clinicians’ Perceptions

Do clinicians’ perceptions give us any more reason to celebrate? Case studies of successful treatment abound. The problem is that clients justify entering psychotherapy by emphasizing their unhappiness and justify leaving by emphasizing their well-being. Therapists treasure compliments from clients as they say good-bye or later express their gratitude, but they hear little from clients who experience only temporary relief and seek out new therapists for their recurring problems. Thus, the same person—with the same recurring anxieties, depression, or marital difficulty—may be a “success” story in several therapists’ files.

Because people enter therapy when they are extremely unhappy, and usually leave when they are less unhappy, most therapists, like most clients, testify to therapy’s success—regardless of the treatment.

Outcome Research

How, then, can we objectively measure the effectiveness of psychotherapy? How can we determine which people and problems are helped, and by what type of psychotherapy?

In search of answers, psychologists have turned to controlled research studies. Similar research in the 1800s transformed the field of medicine. Physicians, skeptical of many of the fashionable treatments (bleeding, purging, infusions of plant and metal substances), began to realize that many patients got better on their own, without these treatments, and that others died despite them. Sorting fact from superstition required observing patients with and without a particular treatment. Typhoid fever patients, for example, often improved after being bled, convincing most physicians that the treatment worked. Not until a control group was given mere bed rest—and 70 percent were observed to improve after five weeks of fever—did physicians learn, to their shock, that the bleeding was worthless (Thomas, 1992).

In psychology, the opening challenge to the effectiveness of psychotherapy was issued by British psychologist Hans Eysenck (1952). Launching a spirited debate, he summarized studies showing that two-thirds of those receiving psychotherapy for non-psychotic disorders improved markedly. To this day, no one disputes that optimistic estimate.

Why, then, are we still debating psychotherapy’s effectiveness? Because Eysenck also reported similar improvement among *untreated* persons, such as those who were on waiting lists. With or without psychotherapy, he said, roughly two-thirds improved noticeably. Time was a great healer.

Later research revealed shortcomings in Eysenck’s analyses; his sample was small (only 24 studies of psychotherapy outcomes in 1952). Today, hundreds of studies are available. The best are *randomized clinical trials*, in which researchers randomly assign people on a waiting list to therapy or to no therapy, and later evaluate everyone, using

meta-analysis a procedure for statistically combining the results of many different research studies.

tests and assessments by others who don't know whether therapy was given. The results of many such studies are then digested by means of **meta-analysis**, a statistical procedure that combines the conclusions of a large number of different studies. Simply said, meta-analyses give us the bottom-line result of lots of studies.

Therapists welcomed the first meta-analysis of some 475 psychotherapy outcome studies (Smith et al., 1980). It showed that the average therapy client ends up better off than 80 percent of the untreated individuals on waiting lists (FIGURE 16.3). The claim is modest—by definition, about 50 percent of untreated people also are better off than the average untreated person. Nevertheless, Mary Lee Smith and her colleagues exulted that “psychotherapy benefits people of all ages as reliably as schooling educates them, medicine cures them, or business turns a profit” (p. 183).

Dozens of subsequent summaries have now examined psychotherapy's effectiveness. Their verdict echoes the results of the earlier outcome studies: *Those not undergoing therapy often improve, but those undergoing therapy are more likely to improve, and to improve more quickly and with less risk of relapse.* Moreover, between treatment sessions for depression and anxiety, many people experience sudden symptom reductions. Those “sudden gains” bode well for long-term improvement (Aderka et al., 2012).

Is psychotherapy also cost-effective? Again, the answer is *Yes*. Studies show that when people seek psychological treatment, their search for other medical treatment drops—by 16 percent in one digest of 91 studies (Chiles et al., 1999). Given the staggering annual cost of psychological disorders and substance abuse—including crime, accidents, lost work, and treatment—psychotherapy is a good investment, much like money spent on prenatal and well-baby care. Both *reduce* long-term costs. Boosting employees' psychological well-being, for example, can lower medical costs, improve work efficiency, and diminish absenteeism.

But note that the claim—that psychotherapy, *on average*, is somewhat effective—refers to no one therapy in particular. It is like reassuring lung-cancer patients that “on average,” medical treatment of health problems is effective. What people want to know is the effectiveness of a *particular* treatment for their specific problems.

RETRIEVAL PRACTICE

- How might the *placebo effect* bias clients' and clinicians' appraisals of the effectiveness of psychotherapies?

ANSWER: The placebo effect is the healing power of belief in a treatment. Patients and therapists who expect a treatment to be effective may believe it was.

▼ FIGURE 16.3

Treatment versus no treatment

These two normal distribution curves based on data from 475 studies show the improvement of untreated people and psychotherapy clients. The outcome for the average therapy client surpassed the outcome for 80 percent of the untreated people. (Data from Smith et al., 1980.)

Which Psychotherapies Work Best?

16-9 Are some psychotherapies more effective than others for specific disorders?

So what can we tell people considering psychotherapy, and those paying for it, about *which* psychotherapy will be most effective for their problem? The statistical summaries and surveys fail to pinpoint any one type of therapy as generally superior (Smith et al., 1977, 1980). Clients seemed equally satisfied, *Consumer Reports* concluded, whether treated by a psychiatrist, psychologist, or social worker; whether seen in a group or individual context; whether the therapist had extensive or relatively limited training and experience (Seligman, 1995). Other studies concur (Barth et al., 2013). There is little if any connection between clinicians' experience, training, supervision, and licensing and their clients' outcomes (Luborsky et al., 2002; Wampold, 2007).

“Whatever differences in treatment efficacy exist, they appear to be extremely small, at best.”

Bruce Wampold et al. (1997)

evidence-based practice clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences.

“Different sores have different salves.”

English proverb

▼ FIGURE 16.4

Evidence-based clinical decision making The ideal clinical decision making is a three-legged stool, upheld by research evidence, clinical expertise, and knowledge of the patient.

So, was the dodo bird in *Alice in Wonderland* right: “Everyone has won and all must have prizes”? Not quite. Some forms of therapy get prizes for particular problems, though there is often an overlapping—or *comorbidity*—of disorders. Behavioral conditioning therapies, for example, have achieved especially favorable results with specific behavior problems, such as bed-wetting, phobias, compulsions, marital problems, and sexual dysfunctions (Baker et al., 2008; Hunsley & DiGiulio, 2002; Shadish & Baldwin, 2005). Psychodynamic therapy has helped treat depression and anxiety (Driessen et al., 2010; Leichsenring & Rabung, 2008; Shedler, 2010b). With mild to moderate depression, non-directive (client-centered) counseling often helps (Cuijpers et al., 2013). And new studies confirm cognitive and cognitive-behavioral therapy’s effectiveness (some say superiority) in coping with anxiety, posttraumatic stress disorder, and depression (Baker et al., 2008; De Los Reyes & Kazdin, 2009; Stewart & Chambless, 2009; Tolin, 2010).

Moreover, we can say that therapy is most effective when the problem is clear-cut (Singer, 1981; Westen & Morrison, 2001). Those who experience phobias or panic, who are unassertive, or who are frustrated by sexual performance problems can hope for improvement. Those with less-focused problems, such as depression and anxiety, usually benefit in the short term but often relapse later. The more specific the problem, the greater the hope.

But no prizes—and little or no scientific support—go to certain other therapies (Arkowitz & Lilienfeld, 2006). We would all therefore be wise to avoid energy therapies that propose to manipulate people’s invisible energy fields, recovered-memory therapies that aim to unearth “repressed memories” of early child abuse (Chapter 8), and rebirthing therapies that engage people in reenacting the supposed trauma of their birth.

As with some medical treatments, it’s possible for psychological treatments to be not only ineffective but also harmful—by making people worse or preventing their getting better (Barlow, 2010; Castonguay et al., 2010; Dimidjian & Hollon, 2010). The National Science and Technology Council cites the Scared Straight program (seeking to deter children and youth from crime) as an example of well-intentioned programs that have proved ineffective or even harmful.

The evaluation question—which therapies get prizes and which do not?—lies at the heart of what some call psychology’s civil war. To what extent should science guide both clinical practice and the willingness of health care providers and insurers to pay for psychotherapy?

On the one side are research psychologists using scientific methods to extend the list of well-defined and validated therapies for various disorders. They decry clinicians who “give more weight to their personal experiences” (Baker et al., 2008). On the other side are non-scientist therapists who view their practice as more art than science, saying that people are too complex and therapy too intuitive to describe in a manual or test in an experiment. Between these two factions stand the science-oriented clinicians, who aim to base practice on evidence and make mental health professionals accountable for effectiveness.

To encourage **evidence-based practice** in psychology, the American Psychological Association and others (2006; Lilienfeld et al., 2013) urge clinicians to integrate the best available research with clinical expertise and with patient preferences and characteristics. Available therapies “should be rigorously evaluated” and then applied by clinicians who are mindful of their skills and of each patient’s unique situation (FIGURE 16.4). Increasingly, insurer and government support for mental health services requires evidence-based practice.

RETRIEVAL PRACTICE

- Therapy is most likely to be helpful for those with problems that _____ (are/ are not) well-defined.

ANSWER: are

Evaluating Alternative Therapies

16-10 How do alternative therapies fare under scientific scrutiny?

The tendency of many abnormal states of mind to return to normal, combined with the placebo effect (the healing power of mere belief in a treatment), creates fertile soil for pseudotherapies. Bolstered by anecdotes, heralded by the media, and broadcast on the Internet, alternative therapies can spread like wildfire. In one national survey, 57 percent of those with a history of anxiety attacks and 54 percent of those with a history of depression had used alternative treatments, such as herbal medicine, massage, and spiritual healing (Kessler et al., 2001).

Testimonials aside, what does the evidence say? This is a tough question, because there is no evidence for or against most of them, though their proponents often feel personal experience is evidence enough. Some, however, have been the subject of controlled research. Let's consider two of these. As we do, remember that sifting sense from nonsense requires the scientific attitude: being skeptical but not cynical, open to surprises but not gullible.

Eye Movement Desensitization and Reprocessing (EMDR)

EMDR (eye movement desensitization and reprocessing) is a therapy adored by thousands and dismissed by thousands more as a sham—"an excellent vehicle for illustrating the differences between scientific and pseudoscientific therapy techniques," suggested James Herbert and seven others (2000). Francine Shapiro (1989, 2007, 2012) developed EMDR while walking in a park and observing that anxious thoughts vanished as her eyes spontaneously darted about. Back in the clinic, she had people imagine traumatic scenes while she triggered eye movements by waving her finger in front of their eyes, supposedly enabling them to unlock and reprocess previously frozen memories. Tens of thousands of mental health professionals from more than 75 countries have since undergone training (EMDR, 2011). Not since the similarly charismatic Franz Anton Mesmer introduced *animal magnetism* (hypnosis) more than two centuries ago (also after feeling inspired by an outdoor experience) has a new therapy attracted so many devotees so quickly.

Does it work? For 84 to 100 percent of single-trauma victims participating in four studies, the answer is *Yes*, reports Shapiro (1999, 2002). Moreover, the treatment need take no more than three 90-minute sessions. The Society of Clinical Psychology task force on empirically validated treatments acknowledges that EMDR is "probably efficacious" for the treatment of nonmilitary posttraumatic stress disorder (Chambless et al., 1997; see also Bisson & Andrew, 2007; Rodenburg et al., 2009; Seidler & Wagner, 2006).

Why, wonder the skeptics, would rapidly moving one's eyes while recalling traumas be therapeutic? Some argue that eye movements serve to relax or distract patients, thus allowing the memory-associated emotions to extinguish (Gunter & Bodner, 2008). Others believe that eye movements in themselves are *not* the therapeutic ingredient (nor is watching high-speed Ping-Pong therapeutic). Trials in which people imagined traumatic scenes and tapped a finger, or just stared straight ahead while the therapist's finger wagged, have also produced therapeutic results (Deville, 2003). EMDR does work better than doing nothing, acknowledge the skeptics (Lilienfeld & Arkowitz, 2007). But skeptics suspect that what is therapeutic is the combination of exposure therapy—repeatedly calling up traumatic memories and reconsolidating them in a safe and reassuring context—and perhaps some placebo effect. Had Mesmer's pseudotherapy been compared with no treatment at all, it, too (thanks to the healing power of positive belief), might have been found "probably efficacious," observed Richard McNally (1999).

"Studies indicate that EMDR is just as effective with fixed eyes. If that conclusion is right, what's useful in the therapy (chiefly behavioral desensitization) is not new, and what's new is superfluous."

Harvard Mental Health Letter, 2002

Light Exposure Therapy

Have you ever found yourself oversleeping, gaining weight, and feeling lethargic during the dark mornings and overcast days of winter? There likely was a survival advantage to your distant ancestors' slowing down and conserving energy during the dark days of winter. For some people, however, especially women and those living far from the equator, the wintertime blahs constitute a seasonal pattern for major depressive disorder. To counteract these dark spirits, National Institute of Mental

Health researchers in the early 1980s had an idea: Give people a timed daily dose of intense light. Sure enough, people reported they felt better.

Was light exposure a bright idea, or another dim-witted example of the placebo effect? Research sheds some light. One study exposed some people with a seasonal pattern in their depression symptoms to 90 minutes of bright light and others to a sham placebo treatment—a hissing “negative ion generator” about which the staff expressed similar enthusiasm (but which was not even turned on). After four weeks, 61 percent of those exposed to morning light had greatly improved, as had 50 percent of those exposed to evening light and 32 percent of those exposed to the placebo (Eastman et al., 1998). Other studies have found that 30 minutes of exposure to 10,000-lux white fluorescent light produced relief for more than half the people receiving morning light therapy (Flory et al., 2010; Terman et al., 1998, 2001). From 20 carefully controlled trials we have a verdict (Golden et al., 2005; Wirz-Justice, 2009): Morning bright light *does* indeed dim depression symptoms for many of those suffering in a seasonal pattern. Moreover, it does so as effectively as taking antidepressant drugs or undergoing cognitive-behavioral therapy (Lam et al., 2006; Rohan et al., 2007). The effects are clear in brain scans; light therapy sparks activity in a brain region that influences the body's arousal and hormones (Ishida et al., 2005).

Christine Brune

Light therapy To counteract winter depression, some people spend time each morning exposed to intense light that mimics natural outdoor light. Light boxes are available from health supply and lighting stores.

RETRIEVAL PRACTICE

- What is evidence-based clinical decision making?
ANSWER: Using this approach, therapists make decisions about treatment based on research evidence, clinical expertise, and knowledge of the client.
- Which of the following alternative therapies HAS shown promise as an effective treatment?
 - a. light therapy
 - b. rebirthing therapies
 - c. recovered-memory therapies
 - d. energy therapies

ANSWER: a

How Do Psychotherapies Help People?

16-11 What three elements are shared by all forms of psychotherapy?

Why have studies found little correlation between therapists' training and experience and clients' outcomes? In search of some answers, clinical researchers have studied the common ingredients of various therapies (Frank, 1982; Goldfried & Padawer, 1982; Strupp, 1986; Wampold, 2001, 2007). Their conclusion: They all offer at least three benefits:

- **Hope for demoralized people** People seeking therapy typically feel anxious, depressed, devoid of self-esteem, and incapable of turning things around. What any therapy offers is the expectation that, with commitment from the therapy seeker, things can and will get better. This belief, apart from any therapeutic technique, may function as a placebo, improving morale, creating feelings of self-efficacy, and diminishing symptoms (Prioleau et al., 1983).
- **A new perspective leading to new behaviors** Every therapy also offers people a plausible explanation of their symptoms and an alternative way of looking at themselves or responding to their world. Armed with a believable fresh perspective, they may approach life with a new attitude, open to making changes in their behaviors and their views of themselves.
- **An empathic, trusting, caring relationship** To say that therapy outcome is unrelated to training and experience is not to say all *therapists* are equally effective. No matter what therapeutic technique they use, effective therapists are empathic people who seek to understand another's experience; who communicate their care and concern to the client; and who earn the client's trust through respectful listening, reassurance, and guidance. Marvin Goldfried and his associates (1998) found such qualities in recorded therapy sessions from 36 recognized master therapists. Some took a cognitive-behavioral approach. Others used psychodynamic principles. Regardless, the striking finding was how *similar* they were. At key moments, the empathic therapists of both persuasions would help clients evaluate themselves, link one aspect of their life with another, and gain insight into their interactions with others.

The emotional bond between therapist and client—the **therapeutic alliance**—helps explain why some therapists are more effective than others (Klein et al., 2003; Wampold, 2001). One U.S. National Institute of Mental Health depression-treatment study confirmed that the most effective therapists were those who were perceived as most empathic and caring and who established the closest therapeutic bonds with their clients (Blatt et al., 1996). That all therapies offer hope through a fresh perspective offered by a caring person is what also enables paraprofessionals (briefly trained caregivers) to assist so many troubled people so effectively (Christensen & Jacobson, 1994).

These three common elements are also part of what the growing numbers of self-help and support groups offer their members. And they are part of what traditional healers have offered (Jackson, 1992). Healers everywhere—special people to whom others disclose their suffering, whether psychiatrists, witch doctors, or shamans—have listened in order to understand and to empathize, reassure, advise, console, interpret, or explain (Torrey, 1986). Such qualities may explain why people who feel supported by close relationships—who enjoy the fellowship and friendship of caring people—are less likely to need or seek therapy (Frank, 1982; O'Connor & Brown, 1984).

* * *

To recap, people who seek help usually improve. So do many of those who do not undergo psychotherapy, and that is a tribute to our human resourcefulness and our capacity to care for one another. Nevertheless, though the therapist's orientation and experience appear not to matter much, people who receive some psychotherapy usually improve more than those who do not. People with clear-cut, specific problems tend to improve the most.

RETRIEVAL PRACTICE

- Those who undergo psychotherapy are _____ (more/less) likely to show improvement than those who do not undergo psychotherapy.

ANSWER: more

Steve Szydlowski/KRT/News.com

A caring relationship Effective counselors, such as this chaplain working aboard a ship, form a bond of trust with the people they are serving.

therapeutic alliance a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem.

Culture and Values in Psychotherapy

16-12 How do culture and values influence the therapist-client relationship?

All therapies offer hope, and nearly all therapists attempt to enhance their clients' sensitivity, openness, personal responsibility, and sense of purpose (Jensen & Bergin, 1988). But therapists also differ from one another and may differ from their clients (Delaney et al., 2007; Kelly, 1990).

These differences can become significant when a therapist from one culture meets a client from another. In North America, Europe, and Australia, for example, most therapists reflect their culture's individualism, which often gives priority to personal desires and identity, particularly for men. Clients who are immigrants from Asian countries, where people are mindful of others' expectations, may have trouble relating to therapies that require them to think only of their own well-being. Such differences help explain minority populations' reluctance to use mental health services, and their tendency to prematurely terminate therapy (Chen et al., 2009; Sue, 2006). In one experiment, Asian-American clients matched with counselors who shared their cultural values (rather than mismatched with those who did not) perceived more counselor empathy and felt a stronger alliance with the counselor (Kim et al., 2005). Recognizing that therapists and clients may differ in their values, communication styles, and language, all American Psychological Association–accredited therapy training programs now provide training in cultural sensitivity and welcome members of underrepresented cultural groups.

Another area of potential values-related conflict is religion. Highly religious people may prefer and benefit from religiously similar therapists (Masters, 2010; Smith et al., 2007; Wade et al., 2006). They may have trouble establishing an emotional bond with a therapist who does not share their values. Because clients tend to adopt their therapists' values (Worthington et al., 1996), some psychologists believe therapists should divulge their values. Today's professional training programs also seek to train therapists from diverse backgrounds who can relate, with sensitivity, to diverse clients.

Finding a Mental Health Professional

16-13 What should a person look for when selecting a therapist?

Life for everyone is marked by a mix of serenity and stress, blessing and bereavement, good moods and bad. So, when should we seek a mental health professional's help? The American Psychological Association offers these common trouble signals:

- Feelings of hopelessness
- Deep and lasting depression
- Self-destructive behavior, such as substance abuse
- Disruptive fears
- Sudden mood shifts
- Thoughts of suicide
- Compulsive rituals, such as hand washing
- Sexual difficulties
- Hearing voices or seeing things that others don't experience

In looking for a therapist, you may want to have a preliminary consultation with two or three. College health centers are generally good starting points, and may offer some free services. You can describe your problem and learn each therapist's treatment approach. You can ask questions about the therapist's values, credentials (TABLE 16.3), and fees. And you can assess your own feelings about each of them. The emotional bond between therapist and client is perhaps the most important factor in effective therapy.

▼ TABLE 16.3
Therapists and Their Training

Type	Therapy Description
Clinical psychologists	Most are psychologists with a Ph.D. (includes research training) or Psy.D. (focuses on therapy) supplemented by a supervised internship and, often, postdoctoral training. About half work in agencies and institutions, half in private practice.
Psychiatrists	Psychiatrists are physicians who specialize in the treatment of psychological disorders. Not all psychiatrists have had extensive training in psychotherapy, but as M.D.s or D.O.s they can prescribe medications. Thus, they tend to see those with the most serious problems. Many have their own private practice.
Clinical or psychiatric social workers	A two-year master of social work graduate program plus postgraduate supervision prepares some social workers to offer psychotherapy, mostly to people with everyday personal and family problems. About half have earned the National Association of Social Workers' designation of clinical social worker.
Counselors	Marriage and family counselors specialize in problems arising from family relations. Clergy provide counseling to countless people. Abuse counselors work with substance abusers and with spouse and child abusers and their victims. Mental health and other counselors may be required to have a two-year master's degree.

REVIEW

Evaluating Psychotherapies

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

- 16-8 Does psychotherapy work? How can we know?
- 16-9 Are some psychotherapies more effective than others for specific disorders?
- 16-10 How do alternative therapies fare under scientific scrutiny?
- 16-11 What three elements are shared by all forms of psychotherapy?
- 16-12 How do culture and values influence the therapist-client relationship?
- 16-13 What should a person look for when selecting a therapist?

Use  LearningCurve to create your personalized study plan, which will direct you to the resources that will help you most in  LaunchPad.

Biomedical Therapies and Preventing Psychological Disorders

PSYCHOTHERAPY IS ONE WAY TO treat psychological disorders. The other is *biomedical therapy*—physically changing the brain’s functioning by altering its chemistry with drugs; affecting its circuitry with electroconvulsive shock, magnetic impulses, or psychosurgery; or influencing its responses with changes in lifestyle. By far the most widely used biomedical treatments today are the drug therapies. Primary care providers prescribe most drugs for anxiety and depression, followed by psychiatrists and, in some states, psychologists.

Drug or placebo effect? For many people, depression lifts while taking an antidepressant drug. But people given a placebo may experience the same effect. Double-blind clinical trials suggest that, especially for those with severe depression, antidepressant drugs do have at least a modest clinical effect.

The New Yorker Collection, 2007, Edward Koren from cartoonbank.com. All Rights Reserved.

“Our psychopharmacologist is a genius.”

Perhaps you can guess an occasional side effect of L-dopa, a drug that raises dopamine levels for Parkinson’s patients: hallucinations.

psychopharmacology the study of the effects of drugs on mind and behavior.

antipsychotic drugs drugs used to treat schizophrenia and other forms of severe thought disorder.

anxiety drugs drugs used to control anxiety and agitation.

Drug Therapies

16-14 What are the drug therapies? How do double-blind studies help researchers evaluate a drug’s effectiveness?

Since the 1950s, discoveries in **psychopharmacology** (the study of drug effects on mind and behavior) have revolutionized the treatment of people with severe disorders, liberating hundreds of thousands from hospital confinement. Thanks to drug therapy, along with efforts to replace hospitalization with community mental health programs, today’s resident population of mental hospitals is a small fraction of what it was a half-century ago. For some who are unable to care for themselves, however, release from hospitals has meant homelessness, not liberation.

Almost any new treatment, including drug therapy, is greeted by an initial wave of enthusiasm as many people apparently improve. But that enthusiasm often diminishes after researchers subtract the rates of (1) normal recovery among untreated persons and (2) recovery due to the placebo effect, which arises from the positive expectations of patients and mental health workers alike. Even mere exposure to advertising about a drug’s supposed effectiveness can increase its effect (Kamenica et al., 2013). So, to evaluate the effectiveness of any new drug, researchers give half the patients the drug, and the other half a similar-appearing placebo. Because neither the staff nor the patients know who gets which, this is called a *double-blind procedure*. The good news: In double-blind studies, some drugs have proven useful.

Antipsychotic Drugs

The revolution in drug therapy for psychological disorders began with the accidental discovery that certain drugs, used for other medical purposes, calmed patients with *psychoses* (disorders in which hallucinations or delusions indicate some loss of contact with reality). These first-generation **antipsychotic drugs**, such as chlorpromazine (sold as Thorazine), dampened responsiveness to irrelevant stimuli. Thus, they provided the most help to patients experiencing positive symptoms of schizophrenia, such as auditory hallucinations and paranoia (Lehman et al., 1998; Lenzenweger et al., 1989).

The molecules of most conventional antipsychotic drugs are similar enough to molecules of the neurotransmitter dopamine to occupy its receptor sites and block its activity. This finding reinforces the idea that an overactive dopamine system contributes to schizophrenia.

Antipsychotics also have powerful side effects. Some produce sluggishness, tremors, and twitches similar to those of Parkinson’s disease (Kaplan & Saddock, 1989). Long-term use of antipsychotics can produce *tardive dyskinesia*, with involuntary movements of the facial muscles (such as grimacing), tongue, and limbs. Although not more effective in controlling schizophrenia symptoms, many of the newer-generation antipsychotics, such as risperidone (Risperdal) and olanzapine (Zyprexa), have fewer of these effects. These drugs may, however, increase the risk of obesity and diabetes (Buchanan et al., 2010; Tiihonen et al., 2009).

Antipsychotics, combined with life-skills programs and family support, have given new hope to many people with schizophrenia (Guo, 2010). Hundreds of thousands of patients have left the wards of mental hospitals and returned to work and to near-normal lives (Leucht et al., 2003).

Antianxiety Drugs

Like alcohol, **antianxiety drugs**, such as Xanax or Ativan, depress central nervous system activity (and so should not be used in combination with alcohol). Antianxiety drugs are often successfully used in combination with psychological therapy. One anti-anxiety drug, the antibiotic D-cycloserine, facilitates the extinction of learned fears in

combination with behavioral treatments. Experiments indicate that the drug enhances the benefits of exposure therapy and helps relieve the symptoms of posttraumatic stress disorder and obsessive-compulsive disorder (Davis, 2005; Kushner et al., 2007).

A criticism sometimes made of the behavior therapies—that they reduce symptoms without resolving underlying problems—is also made of drug therapies. Unlike the behavior therapies, however, these substances may be used as an ongoing treatment. “Popping a Xanax” at the first sign of tension can create a learned response; the immediate relief reinforces a person’s tendency to take drugs when anxious. Antianxiety drugs can also be addictive. After heavy use, people who stop taking them may experience increased anxiety, insomnia, and other withdrawal symptoms.

Over the dozen years at the end of the twentieth century, the rate of outpatient treatment for anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder nearly doubled. The proportion of psychiatric patients receiving medication during that time increased from 52 to 70 percent (Olfson et al., 2004). And the new standard drug treatment for anxiety disorders? Antidepressants.

Antidepressant Drugs

The **antidepressants** were named for their ability to lift people up from a state of depression, and this was their main use until recently. The label is a bit of a misnomer now that these drugs are increasingly being used to successfully treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder (Wetherell et al., 2013). Many of these drugs work by increasing the availability of neurotransmitters, such as norepinephrine or serotonin, which elevate arousal and mood and appear scarce when a person experiences feelings of depression or anxiety. The most commonly prescribed drugs in this group, including Prozac and its cousins Zoloft and Paxil, work by blocking the reabsorption and removal of serotonin from synapses (**FIGURE 16.5**). Given their use in treating disorders other than depression—from anxiety to strokes—these drugs are most often called *SSRIs*—*selective serotonin reuptake inhibitors* (rather than antidepressants) (Kramer, 2011). Some of the older antidepressant drugs work by blocking the reabsorption or breakdown of both norepinephrine and serotonin. Though effective, these dual-action drugs have more potential side effects, such as dry mouth, weight gain, hypertension, or dizzy spells (Anderson, 2000; Mulrow, 1999). Administering them by means of a patch, which bypasses the intestines and liver, helps reduce such side effects (Bodkin & Amsterdam, 2002).

antidepressant drugs drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and post-traumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors*—SSRIs.)

"If this doesn't help you don't worry, it's a placebo."

"No twisted thought without a twisted molecule."

Attributed to psychologist Ralph Gerard

Be advised: Patients with depression who begin taking antidepressants do not wake up the next day singing, "It's a beautiful day!" Although the drugs begin to influence neurotransmission within hours, their full psychological effect often requires four weeks (and may involve a side effect of diminished sexual desire). One possible reason for the delay is that increased serotonin promotes new synapses plus *neurogenesis*—the birth of new brain cells—perhaps reversing stress-induced loss of neurons (Launay et al., 2011). Researchers are also exploring the possibility of quicker-acting antidepressants. One, ketamine, blocks hyperactive receptors for glutamate, a neurotransmitter, and causes a burst of new synapses—but with possible side effects such as hallucinations (Grimm & Scheidegger, 2013; Naughton et al., 2014).

Antidepressant drugs are not the only way to give the body a lift. Aerobic exercise, which calms people who feel anxious and energizes those who feel depressed, does about as much good for most people with mild to moderate depression, and has additional positive side effects. Cognitive therapy, by helping people reverse their habitual negative thinking style, can boost the drug-aided relief from depression and reduce the posttreatment risk of relapse (Hollon et al., 2002; Keller et al., 2000; Vittengl et al., 2007). Better yet, some studies suggest, is to attack depression (and anxiety) from both below and above (Cuijpers et al., 2010; Walkup et al., 2008): Use antidepressant drugs (which work, bottom-up, on the emotion-forming limbic system) in conjunction with cognitive-behavioral therapy (which works, top-down, starting with changed frontal lobe activity).

Researchers generally agree that people with depression often improve after a month on antidepressants. But after allowing for natural recovery and the placebo effect, how big is the drug effect? Not big, report Irving Kirsch and his colleagues (1998, 2002, 2010, 2014). Their analyses of double-blind clinical trials indicate that placebos accounted for about 75 percent of the active drug's effect. In a follow-up review that included unpublished clinical trials, the antidepressant drug effect was again modest (Kirsch et al., 2008). The placebo effect was less for those with severe depression, which made the added benefit of the drug somewhat greater for them. "Given these results, there seems little reason to prescribe antidepressant medication to any but the most severely depressed patients, unless alternative treatments have failed," Kirsch concluded (BBC, 2008). A newer analysis confirms that the antidepressant benefit compared to placebos is "minimal or nonexistent, on average, in patients with mild or moderate symptoms." For those folks, aerobic exercise or psychotherapy is often effective. But among patients with "very severe" depression, the medication advantage becomes "substantial" (Fournier et al., 2010).

"First of all I think you should know that last quarter's sales figures are interfering with my mood-stabilizing drugs."

Mood-Stabilizing Medications

In addition to antipsychotic, antianxiety, and antidepressant drugs, psychiatrists have *mood-stabilizing drugs* in their arsenal. For those suffering the emotional highs and lows of bipolar disorder, the simple salt *lithium* can be an effective mood stabilizer. Australian physician John Cade discovered this in the 1940s when he administered lithium to a patient with severe mania and the patient became well in less than a week (Snyder, 1986). After suffering mood swings for years, about 7 in 10 people with bipolar disorder benefit from a long-term daily dose of this cheap salt, which helps prevent or ease manic episodes and, to a lesser extent, lifts depression (Solomon et al., 1995). Kay Redfield Jamison (1995, pp. 88–89) described the effect:

Lithium prevents my seductive but disastrous highs, diminishes my depressions, clears out the wool and webbing from my disordered thinking, slows me down, gentles me out, keeps me from ruining my career and relationships, keeps me out of a hospital, alive, and makes psychotherapy possible.

Lithium reduces bipolar patients' risk of suicide—to about one-sixth of bipolar patients not taking lithium (Oquendo et al., 2011). Naturally occurring lithium in drinking water has also correlated with lower suicide rates (across 18 Japanese cities and towns) and lower crime rates (across 27 Texas counties) (Ohgami et al., 2009; Schrauzer & Shrestha, 1990, 2010; Terao et al., 2010). Although we do not fully understand why, lithium works. And so does Depakote, a drug originally used to treat epilepsy and more recently found effective in the control of manic episodes associated with bipolar disorder.

RETRIEVAL PRACTICE

- How do researchers evaluate the effectiveness of particular drug therapies?
- The drugs given most often to treat depression are called _____. Schizophrenia is often treated with _____ drugs.

ANSWERS: antidepressants; antipsychotic

Brain Stimulation

16-15 How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive Therapy

A more controversial brain manipulation occurs through shock treatment, or **electroconvulsive therapy (ECT)**. When ECT was first introduced in 1938, the wide-awake patient was strapped to a table and jolted with roughly 100 volts of electricity to the brain, producing racking convulsions and brief unconsciousness. ECT therefore gained a barbaric image, one that lingers. Today's ECT is much kinder and gentler. The patient receives a general anesthetic and a muscle relaxant (to prevent injury from convulsions) before a psychiatrist delivers 30 to 60 seconds of electrical current (FIGURE 16.6). Within 30 minutes, the patient awakens and remembers nothing of the treatment or of the preceding hours. After three such sessions each week for two to four weeks, 80 percent or more of people receiving ECT improve markedly, showing some memory loss for the treatment period but no discernible brain damage. Study after study confirms that ECT is an effective treatment for severe depression in "treatment-resistant" patients who have not responded to drug therapy (Bailine et al., 2010; Fink, 2009; Lima et al., 2013). An editorial in the *Journal of the American Medical Association* concluded that "the results of ECT in treating severe depression are among the most positive treatment effects in all of medicine" (Glass, 2001).

How does ECT alleviate severe depression? After more than 70 years, no one knows for sure. One recipient likened ECT to the smallpox vaccine, which was saving lives before we knew how it worked. Others think of it as rebooting their cerebral computer. But what makes it therapeutic? Perhaps the shock-induced brain seizures calm neural centers where overactivity produces depression. Some research confirms that ECT works by weakening connections in a "hyper-connected" neural hub in the left frontal lobe (Perrin et al., 2012).

electroconvulsive therapy (ECT)

a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient.

▼ FIGURE 16.6

Electroconvulsive therapy Although controversial, ECT is often an effective treatment for depression that does not respond to drug therapy. ("Electroconvulsive" is no longer accurate, because patients are now given a drug that prevents bodily convulsions.)

The medical use of electricity is an ancient practice. Physicians treated the Roman Emperor Claudius (10 B.C.E.–54 C.E.) for headaches by pressing electric eels to his temples.

“I used to . . . be unable to shake the dread even when I was feeling good, because I knew the bad feelings would return. ECT has wiped away that foreboding. It has given me a sense of control, of hope.”

Kitty Dukakis (2006)

A meta-analysis of 17 clinical experiments found that one other stimulation procedure alleviates depression: massage therapy (Hou et al., 2010).

repetitive transcranial magnetic stimulation (rTMS) the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity.

ECT is now administered with briefer pulses, sometimes only to the brain’s right side and with less memory disruption (HMHL, 2007). Yet no matter how impressive the results, the idea of electrically shocking people still strikes many as barbaric, especially given our ignorance about why ECT works. Moreover, about 4 in 10 ECT-treated patients relapse into depression within six months (Kellner et al., 2006). Nevertheless, in the minds of many psychiatrists and patients, ECT is a lesser evil than severe depression’s misery, anguish, and risk of suicide. As research psychologist Norman Endler (1982) reported after ECT alleviated his deep depression, “A miracle had happened in two weeks.”

Alternative Neurostimulation Therapies

Two other neural stimulation techniques—magnetic stimulation and deep-brain stimulation—also treat the depressed brain.

Magnetic Stimulation Depressed moods sometimes improve when repeated pulses surge through a magnetic coil held close to a person’s skull (FIGURE 16.7). The painless procedure—called **repetitive transcranial magnetic stimulation (rTMS)**—is performed on wide-awake patients over several weeks. Unlike ECT, the rTMS procedure produces no brain seizures, memory loss, or other serious side effects aside from possible headaches.

Seven initial studies have found rTMS to be a “promising treatment,” with results comparable to antidepressants (Berlim et al., 2013). How it works is unclear. One possible explanation is that the stimulation energizes the brain’s left frontal lobe (Helmuth, 2001). Repeated stimulation may cause nerve cells to form new functioning circuits through the process of long-term potentiation.

Deep-Brain Stimulation Other patients whose depression has resisted both drugs that flood the body and ECT that jolts at least half the brain have benefited from an experimental treatment pinpointed at a brain depression center. Neuroscientist Helen Mayberg and her colleagues (2005, 2006, 2007, 2009) have been focusing on

▼ FIGURE 16.7

Magnets for the mind Repetitive transcranial magnetic stimulation (rTMS) sends a painless magnetic field through the skull to the surface of the cortex. Pulses can be used to alter activity in various cortical areas.

a neural hub that bridges the thinking frontal lobes to the limbic system. This area, which is overactive in the brain of a depressed or temporarily sad person, calms when treated by ECT or antidepressants. To experimentally excite neurons that inhibit this negative emotion-feeding activity, Mayberg drew upon the deep-brain stimulation technology sometimes used to treat Parkinson's tremors. Since 2003, she and others have treated more than 100 depressed patients with deep brain stimulation to the neural “sadness center.” About one-third reportedly have responded “extremely well” and another 30 percent have modestly improved (Underwood, 2013). Some felt suddenly more aware and became more talkative and engaged; others improved only slightly if at all. Future research will explore whether Mayberg has discovered a switch that can lift depression. Other researchers are following up on reports that deep-brain stimulation can offer relief to people with obsessive-compulsive disorder and with drug and alcohol addictions (Corse et al., 2013; Luigjes et al., 2012; Rabins et al., 2009).

Helen Mayberg, M.D. Psychiatric Neuroimaging and Therapeutics, The Mayberg Lab at Emory University, Atlanta, GA / V. J. Weiden and L. L. Waldron, Annals of the New York Academy of Sciences, 2012. The Human Connectome Project, Boston, MA

RETRIEVAL PRACTICE

- Severe depression that has not responded to other therapy may be treated with _____, which can cause brain seizures and memory loss. More moderate neural stimulation techniques designed to help alleviate depression include _____ magnetic stimulation, and _____ - _____ stimulation.

ANSWERS: electroconvulsive therapy (ECT); repetitive transcranial; deep-brain

A depression switch? By comparing the brains of patients with and without depression, researcher Helen Mayberg identified a brain area (highlighted in red) that appears active in people who are depressed or sad, and whose activity may be calmed by deep-brain stimulation.

Psychosurgery

Because its effects are irreversible, **psychosurgery**—surgery that removes or destroys brain tissue—is the most drastic and least-used biomedical intervention for changing behavior. In the 1930s, Portuguese physician Egas Moniz developed what became the best-known psychosurgical operation: the **lobotomy**. Moniz found that cutting the nerves connecting the frontal lobes with the emotion-controlling centers of the inner brain calmed uncontrollably emotional and violent patients. In what would later become, in others' hands, a crude but quick and easy procedure, a neurosurgeon would shock the patient into a coma, hammer an icepick-like instrument through each eye socket into the brain, and then wiggle it to sever connections running up to the frontal lobes. Between 1936 and 1954, tens of thousands of severely disturbed people were “lobotomized” (Valenstein, 1986).

Although the intention was simply to disconnect emotion from thought, a lobotomy's effect was often more drastic: It usually decreased the person's misery or tension, but also produced a permanently lethargic, immature, uncreative person. During the 1950s, after some 35,000 people had been lobotomized in the United States alone, calming drugs became available and psychosurgery became scorned, as in the saying sometimes attributed to W. C. Fields that “I'd rather have a bottle in front of me than a frontal lobotomy.”

New York Times Co./Getty Images

psychosurgery surgery that removes or destroys brain tissue in an effort to change behavior.

lobotomy a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain.

Failed lobotomy This 1940 photo shows Rosemary Kennedy (center) at age 22 with brother (and future U.S. president) John and sister Jean. A year later her father, on medical advice, approved a lobotomy that was promised to control her reportedly violent mood swings. The procedure left her confined to a hospital with an infantile mentality until her death in 2005 at age 86.

▼ FIGURE 16.8

Mind-body interaction The biomedical therapies assume that mind and body are a unit: Affect one and you will affect the other.

“Forest bathing” In several small studies, Japanese researchers have found that walks in the woods help lower stress hormone and blood pressure levels (Phillips, 2011).

©Randy Farris/Corbis

Today, lobotomies are history. But more precise, microscale psychosurgery is sometimes used in extreme cases. For example, if a patient suffers uncontrollable seizures, surgeons can deactivate the specific nerve clusters that cause or transmit the convulsions. MRI-guided precision surgery is also occasionally done to cut the circuits involved in severe obsessive-compulsive disorder (Carey, 2009, 2011; Sachdev & Sachdev, 1997). Because these procedures are irreversible, they are controversial and neurosurgeons perform them only as a last resort.

Therapeutic Lifestyle Change

16-16 How, by taking care of themselves with a healthy lifestyle, might people find some relief from depression? How does this reflect our being biopsychosocial systems?

The effectiveness of the biomedical therapies reminds us of a fundamental lesson: We find it convenient to talk of separate psychological and biological influences, but everything psychological is also biological (**FIGURE 16.8**). Every thought and feeling depends on the functioning brain. Every creative idea, every moment of joy or anger, every period of depression emerges from the electrochemical activity of the living brain. The influence is two-way: When psychotherapy relieves obsessive-compulsive behavior, PET scans reveal a calmer brain (Schwartz et al., 1996).

Anxiety disorders, obsessive-compulsive disorder, posttraumatic stress disorder, major depressive disorder, bipolar disorder, and schizophrenia are all biological events. As we have seen over and over again, *a human being is an integrated biopsychosocial system*. For years, we have trusted our bodies to physicians and our minds to psychiatrists and psychologists. That neat separation no longer seems valid. Stress affects body chemistry and health. Thus, our lifestyle—our exercise, nutrition, relationships, recreation, relaxation, religious or spiritual engagement, and such—affects our mental health (Walsh, 2011).

That lesson is being applied by Stephen Ilardi (2009) in training seminars promoting *therapeutic lifestyle change*. Human brains and bodies were designed for physical activity and social engagement, he notes. Our ancestors hunted, gathered, and built in groups. Indeed, those whose way of life entails strenuous physical activity, strong community ties, sunlight exposure, and plenty of sleep (think of foraging bands in Papua New Guinea, or Amish farming communities in North America) rarely experience depression. For both children and adults, outdoor activity in natural environments—perhaps a walk in the woods—reduces stress and promotes health (MacKerron & Mourato, 2013; NEEF, 2011; Phillips, 2011). “Simply put: humans were never designed for the sedentary, disengaged, socially isolated, poorly nourished, sleep-deprived pace of twenty-first-century American life.”

The Ilardi team was also impressed by research showing that regular aerobic exercise rivals the healing power of antidepressant drugs, and that a complete night’s sleep boosts mood and energy. So they invited small groups of people with depression to undergo a 12-week training program with the following goals:

- *Aerobic exercise*, 30 minutes a day, at least 3 times weekly (increasing fitness and vitality, stimulating endorphins)

Nicole Hill/Rubberball/Getty Images

- *Adequate sleep*, with a goal of 7 to 8 hours a night (increasing energy and alertness, boosting immunity)
- *Light exposure*, at least 30 minutes each morning with a light box (amplifying arousal, influencing hormones)
- *Social connection*, with less alone time and at least two meaningful social engagements weekly (satisfying the human need to belong)
- *Anti-rumination*, by identifying and redirecting negative thoughts (enhancing positive thinking)
- *Nutritional supplements*, including a daily fish oil supplement with omega-3 fatty acids (supporting healthy brain functioning)

In one study of 74 people, 77 percent of those who completed the program experienced relief from depressive symptoms, compared with 19 percent in those assigned to a treatment-as-usual control condition. Future research will seek to replicate this striking result of lifestyle change, and also to identify which of the treatment components (additively or in some combination) produce the therapeutic effect. In the meantime, there seems little reason to doubt the truth of the Latin adage, *Mens sana in corpore sano*: “A healthy mind in a healthy body.”

TABLE 16.4 summarizes some aspects of the biomedical therapies we’ve discussed.

▼ TABLE 16.4
Comparing Biomedical Therapies

Therapy	Presumed Problem	Therapy Aim	Therapy Technique
<i>Drug therapies</i>	Neurotransmitter malfunction	Control symptoms of psychological disorders.	Alter brain chemistry through drugs.
<i>Brain stimulation</i>	Severe, “treatment-resistant” depression	Alleviate depression that is unresponsive to drug therapy.	Stimulate brain through electroconvulsive shock, magnetic impulses, or deep-brain stimulation.
<i>Psychosurgery</i>	Brain malfunction	Relieve severe disorders.	Remove or destroy brain tissue.
<i>Therapeutic lifestyle change</i>	Stress and unhealthy lifestyle	Restore healthy biological state.	Alter lifestyle through adequate exercise, sleep, and other changes.

RETRIEVAL PRACTICE

- What are some examples of lifestyle changes we can make to enhance our mental health?

ANSWER: Exercise regularly, get enough sleep, get more exposure to light (get outside and/or use a light box), nurture important relationships, redirect negative thinking, and eat a diet rich in omega-3 fatty acids.

Preventing Psychological Disorders and Building Resilience

16-17 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

Psychotherapies and biomedical therapies tend to locate the cause of psychological disorders within the person. We infer that people who act cruelly must be cruel and that people who act “crazy” must be “sick.” We attach labels to such people, thereby distinguishing them from “normal” folks. It follows, then, that we try to treat “abnormal” people by giving them insight into their problems, by changing their thinking, by helping them gain control with drugs.

There is an alternative viewpoint: We could interpret many psychological disorders as understandable responses to a disturbing and stressful society. According to this

view, it is not just the person who needs treatment, but also the person's social context. Better to drain the swamps than swat the mosquitoes. Better to prevent a problem by reforming a sick situation and by developing people's coping competencies than to wait for and treat problems.

Preventive Mental Health

A story about the rescue of a drowning person from a rushing river illustrates this viewpoint: Having successfully administered first aid to the first victim, the rescuer spots another struggling person and pulls her out, too. After a half-dozen repetitions, the rescuer suddenly turns and starts running away while the river sweeps yet another floundering person into view. "Aren't you going to rescue that fellow?" asks a bystander. "Heck no," the rescuer replies. "I'm going upstream to find out what's pushing all these people in."

Preventive mental health is upstream work. It seeks to prevent psychological casualties by identifying and alleviating the conditions that cause them. As George Albee (1986; also Yoshikawa et al., 2012) pointed out, there is abundant evidence that poverty, meaningless work, constant criticism, unemployment, racism, and sexism undermine people's sense of competence, personal control, and self-esteem. Such stresses increase their risk of depression, alcohol use disorder, and suicide.

We who care about preventing psychological casualties should, Albee contended, support programs that alleviate these demoralizing situations. We eliminated smallpox not by treating the afflicted but by inoculating the unafflicted. We conquered yellow fever by controlling mosquitoes. Preventing psychological problems means empowering those who have learned an attitude of helplessness and changing environments that breed loneliness. It means renewing fragile family ties and boosting parents' and teachers' skills at nurturing children's achievements and resulting self-concept. "Everything aimed at improving the human condition, at making life more fulfilling and meaningful, may be considered part of primary prevention of mental or emotional disturbance" (Kessler & Albee, 1975, p. 557). Prevention can sometimes provide a double payoff. People with a strong sense of life's meaning are more engaging socially (Stillman et al., 2011). If we can strengthen people's sense of meaning in life, we may also lessen their loneliness as they grow into more engaging companions.

Among the upstream prevention workers are *community psychologists*. Mindful of how people interact with their environment, they focus on creating environments that support psychological health. Through their research and social action, community psychologists aim to empower people and to enhance their competence, health, and well-being.

Building Resilience

We have seen that lifestyle change can help reverse some of the symptoms of psychological disorders. Might such change also prevent some disorders by building individuals' **resilience**—an ability to cope with stress and recover from adversity? Faced with unforeseen trauma, most adults exhibit resilience. This was true of New Yorkers in the aftermath of the September 11 terror attacks, especially those who enjoyed supportive close relationships and who had not recently experienced other stressful events (Bonanno et al., 2007). More than 9 in 10 New Yorkers, although stunned and grief-stricken by 9/11, did *not* have a dysfunctional stress reaction. By the following January, the stress symptoms of those who did were mostly gone (Person et al., 2006). Even most combat-stressed veterans, most political rebels who have survived torture, and most people with spinal cord injuries do not later exhibit posttraumatic stress disorder (Bonanno et al., 2012; Mineka & Zinbarg, 1996).

"It is better to prevent than to cure."

Peruvian folk wisdom

"Mental disorders arise from physical ones, and likewise physical disorders arise from mental ones."

The Mahabharata, 200 B.C.E.

resilience the personal strength that helps most people cope with stress and recover from adversity and even trauma.

Struggling with challenging crises can even lead to **posttraumatic growth**. Many cancer survivors have reported a greater appreciation for life, more meaningful relationships, increased personal strength, changed priorities, and a richer spiritual life (Tedeschi & Calhoun, 2004). Americans who tried to make sense of the 9/11 terror attacks experienced less distress (Park et al., 2012). Out of even our worst experiences, some good can come. Through preventive efforts, such as community building and personal growth, fewer of us will fall into the rushing river of psychological disorders.

posttraumatic growth positive psychological changes as a result of struggling with extremely challenging circumstances and life crises.

RETRIEVAL PRACTICE

- What is the difference between preventive mental health and psychological or biomedical therapy?

ANSWER: Psychological and biomedical therapies attempt to relieve people's suffering from psychological disorders. Preventive mental health attempts to prevent suffering by identifying and eliminating the conditions that cause disorders.

* * *

If you just finished reading this book, your introduction to psychological science is completed. Our tour of psychological science has taught us much—and you, too?—about our moods and memories, about the reach of our unconscious, about how we flourish and struggle, about how we perceive our physical and social worlds, and about how our biology and culture shape us. Our hope, as your guides on this tour, is that you have shared some of our fascination, grown in your understanding and compassion, and sharpened your critical thinking. And we hope you enjoyed the ride.

With every good wish in your future endeavors,

David G. Myers

REVIEW Biomedical Therapies and Preventing Psychological Disorders

LEARNING OBJECTIVES

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then turn to Appendix C, Complete Chapter Reviews, to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

16-14 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

16-15 How are brain stimulation and psychosurgery used in treating specific disorders?

16-16 How, by taking care of themselves with a healthy lifestyle, might people find some relief from depression? How does this reflect our being biopsychosocial systems?

16-17 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

TERMS AND CONCEPTS TO REMEMBER

RETRIEVAL PRACTICE Test yourself on these terms by trying to write down the definition before flipping back to check your answers.

psychopharmacology, p. 682

antipsychotic drugs, p. 682

antianxiety drugs, p. 682

antidepressant drugs, p. 683

electroconvulsive therapy (ECT), p. 685

repetitive transcranial magnetic stimulation (rTMS), p. 686

psychosurgery, p. 687

lobotomy, p. 687

resilience, p. 690

posttraumatic growth, p. 691

TEST YOURSELF

THERAPY

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Introduction to Therapy and the Psychological Therapies

1. A therapist who helps patients search for the unconscious roots of their problem and offers interpretations of their behaviors, feelings, and dreams, is drawing from
 - a. psychoanalysis.
 - b. humanistic therapies.
 - c. client-centered therapy.
 - d. behavior therapy.
2. _____ therapies are designed to help individuals discover the thoughts and feelings that guide their motivation and behavior.
3. Compared with psychoanalysts, humanistic therapists are more likely to emphasize
 - a. hidden or repressed feelings.
 - b. childhood experiences.
 - c. psychological disorders.
 - d. self-fulfillment and growth.
4. A therapist who restates and clarifies the client's statements is practicing _____.
5. The goal of behavior therapy is to
 - a. identify and treat the underlying causes of the problem.
 - b. improve learning and insight.
 - c. eliminate the unwanted behavior.
 - d. improve communication and social sensitivity.
6. Behavior therapies often use _____ techniques such as systematic desensitization and aversive conditioning to encourage clients to produce new responses to old stimuli.
7. The technique of _____ teaches people to relax in the presence of progressively more anxiety-provoking stimuli.
8. After a near-fatal car accident, Rico developed such an intense fear of driving on the freeway that he takes lengthy alternative routes to work each day. Which psychological therapy might best help Rico overcome his phobia, and why?
9. At a treatment center, people who display a desired behavior receive coins that they can later exchange for other rewards. This is an example of a(n) _____.
10. Cognitive therapy has been especially effective in treating
 - a. nail biting.
 - b. phobias.
 - c. alcohol use disorder.
 - d. depression.
11. _____ - _____ therapy helps people to change their self-defeating ways of thinking and to act out those changes in their daily behavior.

12. In family therapy, the therapist assumes that
- only one family member needs to change.
 - each person's actions trigger reactions from other family members.
 - dysfunctional families must improve their interactions or give up their children.
 - all of the above are true.

Evaluating Psychotherapies

13. The most enthusiastic or optimistic view of the effectiveness of psychotherapy comes from
- outcome research.
 - randomized clinical trials.
 - reports of clinicians and clients.
 - a government study of treatment for depression.
14. Studies show that _____ therapy is the most effective treatment for most psychological disorders.
- behavior
 - humanistic
 - psychodynamic
 - no one type of
15. What are the three components of evidence-based practice?
16. How does the placebo effect bias patients' attitudes about the effectiveness of drug therapies?

Biomedical Therapies and Preventing Psychological Disorders

17. Some antipsychotic drugs, used to calm people with schizophrenia, can have unpleasant side effects, most notably
- hyperactivity.
 - convulsions and momentary memory loss.
 - sluggishness, tremors, and twitches.
 - paranoia.
18. Drugs like Xanax and Ativan, which depress central nervous system activity, can become addictive when used as ongoing treatment. These drugs are referred to as _____ drugs.
19. A simple salt that often brings relief to patients suffering the highs and lows of bipolar disorder is _____.
20. When drug therapies have not been effective, electroconvulsive therapy (ECT) may be used as treatment, largely for people with
- severe obsessive-compulsive disorder.
 - severe depression.
 - schizophrenia.
 - anxiety disorders.
21. An approach that seeks to identify and alleviate conditions that put people at high risk for developing psychological disorders is called
- deep-brain stimulation.
 - the mood-stabilizing perspective.
 - spontaneous recovery.
 - preventive mental health.

Find answers to these questions in Appendix D, in the back of the book.

Psychology at Work

A-1 What is *flow*, and what are the three subfields of industrial-organizational psychology?

For most of us, work is life's biggest single waking activity. To live is to work. Work helps satisfy several levels of need identified in Abraham Maslow's (1970) hierarchy of needs. Work supports us. Work connects us. Work defines us. Meeting someone for the first time, and wondering who they are, we may ask, "So, what do you do?"

Individuals across various occupations vary in their attitudes toward their work. Some view their work as a *job*, an unfulfilling but necessary way to make money. Others view their work as a *career*, an opportunity to advance from one position to a better position. The rest—those who view their work as a *calling*, a fulfilling and socially useful activity—report the highest satisfaction with their work and with their lives (Dik & Duffy, 2012; Wrzesniewski et al., 1997, 2001).

This finding would not surprise Mihaly Csikszentmihalyi [chick-SENT-me-hi] (1990, 1999). He observed that people's quality of life increases when they are purposefully engaged. Between the anxiety of being overwhelmed and stressed, and the apathy of being underwhelmed and bored, lies a zone in which people experience **flow**. Can you recall being in a zoned-out flow state while texting or playing a video game? If so, then perhaps you can sympathize with the two Northwest Airlines pilots who in 2009 were so focused on their laptops that they missed Earth-to-pilot messages from their control tower. The pilots flew 150 miles past their Minneapolis destination—and lost their jobs.

Csikszentmihalyi formulated the flow concept after studying artists who spent hour after hour painting or sculpting with focused concentration. Immersed in a project, they worked as if nothing else mattered, and then, when finished, they promptly forgot about it. The artists seemed driven less by external rewards—money, praise, promotion—than by the intrinsic rewards of creating their art.

Csikszentmihalyi's later observations, of people from varied occupations and countries, and of all ages, confirmed an overriding principle: It's exhilarating to flow with an activity that fully engages our skills. Flow experiences boost our sense of self-esteem, competence, and well-being. Idleness may sound like bliss, but purposeful work enriches our lives. Busy people are happier (Hsee et al., 2010; Robinson & Martin, 2008). One research team interrupted people on about a quarter-million occasions

Sometimes, Gene Weingarten noted (2002), a humor writer knows "when to just get out of the way." Here are some sample job titles from the U.S. Department of Labor *Dictionary of Occupational Titles*: animal impersonator, human projectile, banana ripening-room supervisor, impregnator, impregnator helper, dope sprayer, finger waver, rug scratcher, egg smeller, bottom buffer, cookie breaker, brain picker, hand pouncer, bosom presser, and mother repairer.

Have you ever noticed that when you are immersed in an activity, time flies? And that when you are watching the clock, it seems to move more slowly? French researchers have confirmed that the more we attend to an event's duration, the longer it seems to last (Couli et al., 2004).

flow a completely involved, focused state of consciousness, with diminished awareness of self and time, resulting from optimal engagement of one's skills.

Matthew Palmer/Hill Street Studios/Blend Images/Brand X Pictures/Getty Images

Life disrupted Playing and socializing online are ever-present sources of distraction. It takes energy to resist checking our phones, and time to refocus mental concentration after each disruption. Such regular interruptions disrupt flow, so it's a good idea to instead schedule breaks for checking our handheld devices.

The modern workforce The editorial team that supports the creation of this book and its teaching package works both in-house and from far-flung places. Clockwise from top left are Nancy Fleming in Massachusetts, Rachel Losh in New York, Betty Probert in Florida, Christine Brune in Alaska, Trish Morgan in Alberta, Tracey Kuehn in New York, and Kathryn Brownson in Michigan.

industrial-organizational (I/O) psychology the application of psychological concepts and methods to optimizing human behavior in workplaces.

personnel psychology an I/O psychology subfield that focuses on employee recruitment, selection, placement, training, appraisal, and development.

organizational psychology an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change.

human factors psychology an I/O psychology subfield that explores how people and machines interact and how machines and physical environments can be made safe and easy to use.

(using a smart-phone app), and found people’s minds wandering 47 percent of the time. They were, on average, happier when *not* mind wandering (Killingsworth & Gilbert, 2010).

In many nations work has changed, from farming to manufacturing to *knowledge work*. More and more work is outsourced to temporary employees and consultants or to workers communicating electronically from off-site workplaces. As work has changed, have our attitudes toward our work also changed? Has our satisfaction with work increased or decreased? Has the *psychological contract*—the sense of mutual obligations between workers and employers—become more or less trusting and secure? These are among the questions that fascinate psychologists who study work-related behavior.

Industrial-organizational (I/O) psychology applies psychology’s principles to the workplace (TABLE A.1). Here we consider three of I/O psychology’s subfields:

- **Personnel psychology** applies psychology’s methods and principles to selecting and evaluating workers. Personnel psychologists match people with jobs, by identifying and placing well-suited candidates.

- **Organizational psychology** considers how work environments and management styles influence worker motivation, satisfaction, and productivity. Organizational psychologists modify jobs and supervision in ways that boost morale and productivity.
- **Human factors psychology** explores how machines and environments can be optimally designed to fit human abilities. Human factors psychologists study people’s natural perceptions and inclinations to create user-friendly machines and work settings.

▼ **TABLE A.1**
I/O Psychology at Work

As scientists, consultants, and management professionals, industrial-organizational (I/O) psychologists are found working in varied areas:

Personnel Psychology	Organizational Psychology
Selecting and placing employees • Developing and validating assessment tools for selecting, placing, and promoting workers • Analyzing job content • Optimizing worker placement Training and developing employees • Identifying needs • Designing training programs • Evaluating training programs Appraising performance • Developing criteria • Measuring individual performance • Measuring organizational performance	Developing organizations • Analyzing organizational structures • Maximizing worker satisfaction and productivity • Facilitating organizational change Enhancing quality of work life • Expanding individual productivity • Identifying elements of satisfaction • Redesigning jobs Human Factors (Engineering) Psychology • Designing optimum work environments • Optimizing person-machine interactions • Developing systems technologies

RETRIEVAL PRACTICE

- What is the value of finding flow in our work?

ANSWER: We become more likely to view our work as fulfilling and socially useful.

Personnel Psychology

A-2 How do personnel psychologists help organizations with employee selection, work placement, and performance appraisal?

Psychologists can assist organizations at various stages of selecting and assessing employees. They may help identify needed job skills, decide upon selection methods, recruit and evaluate applicants, introduce and train new employees, and appraise their performance.

Matching Interests to Work

“So what interests you?” we may ask a new acquaintance. When faculty advisers or vocational counselors probe further, we may ask: “What do you love to do? What are you doing when time just flies—and what are you doing when time seems to stand still?” By exploring what someone enjoys, we seek to discern what academic and vocational pursuits might fit the student’s interests. Much work is hard or tedious labor that people do solely for self-support. But the best job is one that pays you to do what you love—be it doing things with your hands, thinking of solutions, expressing yourself creatively, assisting people, being in charge, or working with data. Do what you love and you will love what you do.

A career counseling science aims, first, to assess people’s differing values, personalities, and, especially, interests, which are remarkably stable (Dik & Rottinghaus, 2013). (Your job may change, but your interests today will likely still be your interests in 10 years.) Second, it aims to alert people to well-matched vocations—vocations with a good *person-environment fit*. One study assessed 400,000 high school students’ interests and then followed them over time. The take-home finding: “Interests uniquely predict academic and career success over and above cognitive ability and personality” (Rounds & Su, 2014). The power of well-matched interests to predict income, for example, “greatly exceeded the contributions of ability and personality.” Sixty other studies confirm the point both for students in school and workers on the job: Interests predict both performance and persistence (Nye et al., 2012).

Harnessing Strengths

As a new AT&T human resources executive, psychologist Mary Tenopyr (1997) was assigned to solve a problem: Customer-service representatives were failing at a high rate. After concluding that many of the hires were ill-matched to the demands of their new job, Tenopyr developed a new selection instrument:

1. She asked new applicants to respond to various test questions (without as yet making any use of their responses).
2. She followed up later to assess which of the applicants excelled on the job.
3. She identified the earlier test questions that best predicted success.

The happy result of her data-driven work was a new test that enabled AT&T to identify likely-to-succeed representatives. Personnel selection techniques such as this one aim to match people’s strengths with work that enables them and their organization to flourish. Marry the strengths of people with the tasks of organizations and the result is often prosperity and profit.

Your strengths are any enduring qualities that can be productively applied. Are you naturally curious? Persuasive? Charming? Persistent? Competitive? Analytical? Empathic? Organized? Articulate? Neat? Mechanical? Any such trait, if matched with suitable work, can function as a strength (Buckingham, 2007).

Alvin Langdon Coburn/George Eastman House/Getty Images

Artistic strengths At age 21, Henri Matisse was a sickly and often depressed lawyer's clerk. When his mother gave him a box of paints to cheer him up one day, he felt the darkness lift and his energy surge. He began to fill his days with painting and drawing and went on to art school and a life as one of the world's great painters. For Matisse, doing art felt like "a comfortable armchair." That is how exercising our strengths often feels.

Gallup researchers Marcus Buckingham and Donald Clifton (2001) have argued that the first step to a stronger organization is instituting a *strengths-based selection system*. Thus, as a manager, you would first identify a group of the most effective people in any role—the ones you would want to hire more of—and compare their strengths with those of a group of the least effective people in that role. In defining these groups, you would try to measure performance as objectively as possible. In one Gallup study of more than 5000 telecommunications customer-service representatives, those evaluated most favorably by their managers were strong in "harmony" and "responsibility," while those actually rated most effective by customers were strong in energy, assertiveness, and eagerness to learn.

An example: If you needed to hire new people in software development, and you had discovered that your best software developers are analytical, disciplined, and eager to learn, you would focus employment ads less on experience than on the identified strengths. Thus "Do you take a logical and systematic approach to problem solving [*analytical*]? Are you a perfectionist who strives for timely completion of your projects [*disciplined*]? Do you want to master Java, C++, and PHP [*eager to learn*]? If you can say *Yes* to these questions, then please call . . ."

Identifying people's strengths and matching those strengths to work is a first step toward workplace effectiveness. To assess applicants' strengths and decide who is best suited to the job, personnel managers use various tools (Sackett & Lievens, 2008), including ability tests, personality tests, and behavioral observations in "assessment centers" that test applicants on tasks that mimic the job they seek.

Discovering Your Strengths

You can use some of the techniques personnel psychologists have developed to identify your own strengths and pinpoint types of work that will likely prove satisfying and successful. Buckingham and Clifton (2001) have suggested asking yourself these questions:

- What activities give me pleasure? Bringing order out of chaos? Playing host? Helping others? Challenging sloppy thinking?
- What activities leave me wondering, "When can I do this again?" rather than, "When will this be over?"
- What sorts of challenges do I relish? And which do I dread?
- What sorts of tasks do I learn easily? And which do I struggle with?

Some people find themselves in flow—their skills engaged and time flying—when teaching or selling or writing or cleaning or consoling or creating or repairing. If an activity feels good, if it comes easily, if you look forward to it, then look deeper and see your strengths at work. For a free (requires registration) assessment of your personal strengths, visit www.authentic happiness.sas.upenn.edu and select the "Brief Strengths Test."

The U.S. Department of Labor also offers a vocational interest questionnaire via its Occupational Information Network (O*NET). At www.mynextmove.org/explore/ip you will need about 10 minutes to respond to 60 items, indicating how much you would like or dislike activities ranging from building kitchen cabinets to playing a musical instrument. You will then receive feedback on how strongly your responses reflect six interest types specified by vocational psychologist John L. Holland (1996): *realistic* (hands-on doers), *investigative* (thinkers), *artistic* (creators), *social* (helpers, teachers), *enterprising* (persuaders, deciders), and *conventional* (organizers). Finally, depending on how much training you indicate being willing to undertake, you will be shown occupations—selected from a national database of 900+ occupations—that are

congruent with your interest pattern. A more comprehensive (and fee-based) online service (called VIP) assesses people's values, interests, and personalities; suggests occupations; and connects people to job listings at www.jobzology.com.

Satisfied and successful people devote far less time to correcting their deficiencies than to accentuating their strengths. Top performers are “rarely well rounded,” Buckingham and Clifton found (p. 26). Instead, they have sharpened their existing skills. Given the persistence of our traits and temperaments, we should focus not on our deficiencies, but rather on identifying and employing our talents. There may be limits to the benefits of assertiveness training if you are extremely shy, of public speaking courses if you tend to be nervous and soft-spoken, or of drawing classes if you express your artistic side in stick figures.

Identifying your talents can help you recognize the activities you learn quickly and find absorbing. Knowing your strengths, you can develop them further.

Do Interviews Predict Performance?

Most interviewers feel confident of their ability to predict long-term job performance from a get-acquainted interview. What's therefore shocking is how error prone interviewers' predictions are when predicting job or graduate school success. From their review of 85 years of personnel-selection research, I/O psychologists Frank Schmidt and John Hunter (1998; Schmidt, 2002) determined that for all but less-skilled jobs, general mental ability best predicts on-the-job performance. Subjective overall evaluations from informal interviews are more useful than handwriting analysis (which is worthless). But informal interviews are less informative than aptitude tests, work samples, job knowledge tests, and past job performance. If there's a contest between what our gut tells us about someone and what test scores, work samples, and past performance tell us, we should distrust our gut (Highhouse, 2008).

“Interviews are a terrible predictor of performance.”

Laszlo Bock, Google's Vice President,
People Operations, 2007

Unstructured Interviews and the Interviewer Illusion

Traditional *unstructured interviews* can provide a sense of someone's personality—their expressiveness, warmth, and verbal ability, for example. But these informal interviews also give interviewees considerable power to control the impression they are making in the interview situation (Barrick et al., 2009). Why, then, do many interviewers have such faith in their ability to discern interviewee's fitness for a job? “I have excellent interviewing skills, so I don't need reference checking as much as someone who doesn't have my ability to read people,” I/O consultants often hear. This tendency to overrate their ability to predict people's futures is called the *interviewer illusion* (Dana et al., 2013; Nisbett, 1987). Five factors explain the gap between interviewers' overconfidence and the resulting reality:

- *Interviewers presume that people are what they seem to be in the interview situation.* An unstructured interview may create a false impression of a person's behavior toward others in different situations. As personality psychologists explain, when meeting others, we discount the enormous influence of varying situations and mistakenly presume that what we see is what we will get. But research on everything from chattiness to conscientiousness reveals that how we behave reflects not only our enduring traits, but also the details of the particular situation (such as wanting to impress in a job interview).
- *Interviewers' preconceptions and moods color how they perceive interviewees' responses* (Cable & Gilovich, 1998; Macan & Dipboye, 1994). If interviewers instantly like a person who perhaps is similar to themselves, they may interpret the

“Between the idea and reality . . . falls the shadow.”

T. S. Eliot, *The Hollow Men*, 1925

structured interviews interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales.

person’s assertiveness as indicating “confidence” rather than “arrogance.” If told certain applicants have been prescreened, interviewers are disposed to judge them more favorably.

- *Interviewers judge people relative to those interviewed just before and after them* (Simonsohn & Gino, 2013). If you are being interviewed for business or medical school, hope for a time when the other interviewees have been weak.
- *Interviewers more often follow the successful careers of those they have hired than the successful careers of those they have rejected.* This missing feedback prevents interviewers from getting a reality check on their hiring ability.
- *Interviews disclose the interviewee’s good intentions, which are less revealing than habitual behaviors* (Ouellette & Wood, 1998). Intentions matter. People can change. But the best predictor of the person we will be is the person we have been. Compared with work-avoiding university students, those who engage in their tasks are more likely, a decade and more later, to be engaged workers (Salmela-Aro et al., 2009). Educational attainments predict job performance partly because people who have shown up for school each day and done their tasks also tend to show up for work and do their tasks (Ng & Feldman, 2009). Wherever we go, we take ourselves along.

Hoping to improve prediction and selection, personnel psychologists have put people in simulated work situations, sought information on past performance, aggregated evaluations from multiple interviews, administered tests, and developed job-specific interviews.

Structured Interviews

Unlike casual conversation aimed at getting a feel for someone, **structured interviews** offer a disciplined method of collecting information. A personnel psychologist may analyze a job, script questions, and train interviewers. The interviewers then put the same questions, in the same order, to all applicants, and rate each applicant on established scales.

In an unstructured interview, someone might ask, “How organized are you?” “How well do you get along with people?” or “How do you handle stress?” Street-smart applicants know how to score high: “Although I sometimes drive myself too hard, I handle stress by prioritizing and delegating, and by making sure I leave time for sleep and exercise.”

By contrast, structured interviews pinpoint strengths (attitudes, behaviors, knowledge, and skills) that distinguish high performers in a particular line of work. The process includes outlining job-specific situations and asking candidates to explain how they would handle them, and how they handled similar situations in their prior employment. “Tell me about a time when you were caught between conflicting demands, without time to accomplish both. How did you handle that?”

To reduce memory distortions and bias, the interviewer takes notes and makes ratings as the interview proceeds and avoids irrelevant and follow-up questions. The structured interview therefore feels less warm, but that can be explained to the applicant: “This conversation won’t typify how we relate to each other in this organization.”

A review of 150 findings revealed that structured interviews had double the predictive accuracy of unstructured seat-of-the-pants interviews (Schmidt & Hunter, 1998; Wiesner & Cronshaw, 1988). Structured interviews also reduce bias, such as against overweight applicants (Kutcher & Bragger, 2004). Thanks partly to its greater reliability and partly to its job-analysis focus, the predictive power of one structured interview is roughly equal to that of the average judgment from three or four unstructured interviews (Huffcutt et al., 2001; Schmidt & Zimmerman, 2004).

If, instead, we let our intuitions bias the hiring process, noted Malcolm Gladwell (2000, p. 86), then “all we will have done is replace the old-boy network, where you hired your nephew, with the new-boy network, where you hire whoever impressed you

most when you shook his hand. Social progress, unless we're careful, can merely be the means by which we replace the obviously arbitrary with the not so obviously arbitrary."

To recap, personnel psychologists assist organizations in analyzing jobs, recruiting well-suited applicants, and selecting and placing employees. They also appraise employees' performance (FIGURE A.1)—the topic we turn to next.

▼ FIGURE A.1
Personnel psychologists' tasks Personnel psychologists consult in human resources activities, from job definition to employee appraisal.

Appraising Performance

Performance appraisal serves organizational purposes: It helps decide who to retain, how to appropriately reward and pay people, and how to better harness employee strengths, sometimes with job shifts or promotions. Performance appraisal also serves individual purposes: Feedback affirms workers' strengths and helps motivate needed improvements.

Performance appraisal methods include

- *checklists* on which supervisors simply check specific behaviors that describe the worker ("always attends to customers' needs," "takes long breaks").
- *graphic rating scales* on which a supervisor checks, perhaps on a five-point scale, how often a worker is dependable, productive, and so forth.
- *behavior rating scales* on which a supervisor checks scaled behaviors that describe a worker's performance. If rating the extent to which a worker "follows procedures," the supervisor might mark the employee somewhere between "often takes short-cuts" and "always follows established procedures" (Levy, 2003).

In some organizations, performance feedback comes not only from supervisors but also from all organizational levels. If you join an organization that practices *360-degree feedback* (FIGURE A.2), you will rate yourself, your manager, and your other colleagues, and you will be rated by your manager, other colleagues, and customers (Green, 2002). The net result is often more open communication and more complete appraisal.

Performance appraisal, like other social judgments, is vulnerable to bias (Murphy & Cleveland, 1995). *Halo errors* occur when one's overall evaluation of an employee, or of a personal trait such as their friendliness, biases ratings of their specific work-related behaviors, such as their reliability. *Leniency* and *severity errors* reflect evaluators' tendencies to be either too easy or too harsh on everyone. *Recency errors* occur when raters focus only on easily remembered recent behavior. By using multiple raters and developing objective, job-relevant performance measures, personnel psychologists seek to support their organizations while also helping employees perceive the appraisal process as fair.

▼ FIGURE A.2
360-degree feedback With multi-source 360-degree feedback, our knowledge, skills, and behaviors are rated by ourselves and surrounding others. Professors, for example, may be rated by their department chairs, their students, and their colleagues. After receiving all these ratings, professors discuss the 360-degree feedback with their department chair.

RETRIEVAL PRACTICE

- A human resources director explains to you that “I don’t bother with tests or references. It’s all about the interview.” Based on I/O research, what concerns does this raise?

ANSWER: (1) Interviewers may presume people are what they seem to be in interviews. (2) Interviewers’ preconceptions and moods color how they perceive interviewees’ responses. (3) Interviewers judge people relative to other recent interviewees. (4) Interviewers tend to track the successful careers of those they hire, not the successful careers of those they reject. (5) Interviewers tend to disclose prospective workers’ good intentions, not their habitual behaviors.

Organizational Psychology

A-3 What is the role of organizational psychologists?

The appraisal of work and the matching of interests and talents to work matter, but so does overall motivation. Organizational psychologists assist with efforts to motivate and engage employees.

Satisfaction and Engagement

Partly because work is such a big part of life, I/O psychologists study employee satisfaction. Satisfaction with work feeds satisfaction with life (Bowling et al., 2010). Moreover, as health psychologists tell us, decreased job stress feeds improved health.

Satisfied employees also contribute to successful organizations. Positive moods at work enhance creativity, persistence, and helpfulness (Ford et al., 2011; Shockley et al., 2012). Are engaged, happy workers also less often absent? Less likely to quit? Less prone to theft? More punctual? More productive? Conclusive evidence of satisfaction’s benefits is, some have said, the Holy Grail of I/O psychology. Statistical digests of prior

“The only place success comes before work is in the dictionary.”

Former Green Bay Packers football coach
Vince Lombardi

Doing well while doing good—“The Great Experiment” At the end of the 1700s, the New Lanark, Scotland, cotton mill had more than 1000 workers. Many were children drawn from Glasgow’s poorhouses. They worked 13-hour days and lived in grim conditions.

On a visit to Glasgow, Welsh-born Robert Owen—an idealistic young cotton-mill manager—chanced to meet and marry the mill owner’s daughter. Owen and some partners purchased the mill and on the first day of the 1800s began what he said was “the most important experiment for the happiness of the human race that had yet been instituted at any time in any part of the world” (Owen, 1814). The exploitation of child and adult labor was, he observed, producing unhappy and inefficient workers. So he undertook numerous innovations: a nursery for preschool children, education for older

Courtesy of New Lanark Trust

children (with encouragement rather than corporal punishment), Sundays off, health care, paid sick days, unemployment pay for days when the mill could not operate, and a company store selling goods at reduced prices.

He also innovated a goals- and worker-assessment program that included detailed records of daily productivity and costs but with “no beating, no abusive language.”

The ensuing commercial success fueled a humanitarian reform movement. By 1816, with decades of profitability still ahead, Owen believed he had demonstrated “that society may be formed so as to exist

without crime, without poverty, with health greatly improved, with little if any misery, and with intelligence and happiness increased a hundredfold.” Although his Utopian vision has not been fulfilled, Owen’s great experiment laid the groundwork for employment practices that have today become accepted in much of the world.

Darren Green/The Grand Rapids Press/Landov

An engaged employee Mohamed Mamow, left, was joined by his employer in saying the Pledge of Allegiance as he became a U.S. citizen. Mamow and his wife met in a Somali refugee camp and now are parents of five children, whom he supports by working as a machine operator. Mindful of his responsibility—"I don't like to lose my job. I have a responsibility for my children and my family"—he arrives for work a half hour early and tends to every detail on his shift. "He is an extremely hard-working employee," noted his employer, and "a reminder to all of us that we are really blessed" (Roelofs, 2010).

research have found a modest positive correlation between individual job satisfaction and performance (Judge et al., 2001; Ng et al., 2009; Parker et al., 2003). In one analysis of 4500 employees at 42 British manufacturing companies, the most productive workers tended to be those in satisfying work environments (Patterson et al., 2004). Happy workers are usually good workers. But does satisfaction *produce* better job performance? The debate continues.

Nevertheless, some organizations do have a knack for cultivating more engaged and productive employees. In the United States, the *Fortune* "100 Best Companies to Work For" have also produced markedly higher-than-average returns for their investors (Fulmer et al., 2003). Other positive data come from the biggest-ever I/O study, an analysis of Gallup data from more than 198,000 employees (TABLE A.2) in nearly 8000 business units of 36 large companies (including some 1100 bank branches, 1200 stores, and 4200 teams

▼ TABLE A.2

The Gallup Workplace Audit

Overall satisfaction—On a 5-point scale, where 5 is extremely satisfied and 1 is extremely dissatisfied, how satisfied are you with (*name of company*) as a place to work? _____. On a scale of 1 to 5, where 1 is strongly disagree and 5 is strongly agree, please indicate your agreement with the following items:

1. I know what is expected from me at work.
2. I have the materials and equipment I need to do my work right.
3. At work, I have the opportunity to do what I do best every day.
4. In the last seven days, I have received recognition or praise for doing good work.
5. My supervisor, or someone at work, seems to care about me as a person.
6. There is someone at work who encourages my development.
7. At work, my opinions seem to count.
8. The mission/purpose of my company makes me feel my job is important.
9. My associates (fellow employees) are committed to doing quality work.
10. I have a best friend at work.
11. In the last six months, someone at work has talked to me about my progress.
12. This last year, I have had opportunities at work to learn and grow.

▼ TABLE A.3
Three Types of Employees

<i>Engaged:</i> working with passion and feeling a profound connection to their company or organization.
<i>Not engaged:</i> putting in the time but investing little passion or energy into their work.
<i>Actively disengaged:</i> unhappy workers undermining what their colleagues accomplish.

Source: Adapted from Gallup via Crabtree, 2005.

or departments). James Harter, Frank Schmidt, and Theodore Hayes (2002) explored correlations between various measures of organizational success and *employee engagement*—the extent of workers’ involvement, enthusiasm, and identification with their organizations (TABLE A.3). They found that engaged workers (compared to disengaged workers who are just putting in time) knew what was expected of them, had what they needed to do their work, felt fulfilled in their work, had regular opportunities to do what they do best, perceived that they were part of something significant, and had opportunities to learn and develop. They also found that business units with engaged employees had more loyal customers, lower turnover rates, higher productivity, and greater profits.

But what causal arrows explain this correlation between business success and employee morale and engagement? Does success boost morale, or does high morale boost success? In a follow-up longitudinal study of 142,000 workers, researchers found that, over time, employee attitudes predicted future business success (more than the other way around) (Harter et al., 2010). Another analysis compared companies with top-quartile versus below-average employee engagement levels. Over a three-year period, earnings grew 2.6 times faster for the companies with highly engaged workers (Ott, 2007).

Managing Well

A-4 What are some effective leadership techniques?

Every leader dreams of managing in ways that enhance people’s satisfaction, engagement, and productivity and their organization’s success. Effective leaders harness job-relevant strengths, set goals, and choose an appropriate leadership style.

Harnessing Job-Relevant Strengths

“The major challenge for CEOs over the next 20 years will be the effective deployment of human assets,” observed Marcus Buckingham (2001). That challenge is “about psychology. It’s about getting [individuals] to be more productive, more focused, more fulfilled than [they were] yesterday.” The first step, he and others have maintained, is selecting the right people, followed by discerning employees’ natural talents, adjusting work roles to suit those talents, and developing talents into great strengths (FIGURE A.3). Consider the faculty at a given college or university. Should everyone be expected to teach the same course load, advise the same number of students, serve on the same number of committees, and engage in the same amount of research? Or should each job description be tailored to harness a specific person’s unique strengths?

Given that our temperament and our traits tend to follow us through our lives, managers would be wise to spend less time trying to instill talents that are not there and more time developing and drawing out those that are there (Tucker, 2002). Managers who excel

- start by helping people identify and measure their talents.
- match tasks to talents and then give people freedom to do what they do best.

- care how their people feel about their work.
- reinforce positive behaviors through recognition and reward.

Thus, rather than focusing on weaknesses and packing people off to training seminars to fix those problems, effective managers focus training time on educating people about their strengths and building upon them (which means not promoting people into roles ill-suited to their strengths). In Gallup surveys, 77 percent of engaged workers, and only 23 percent of not-engaged workers, strongly agreed that “my supervisor focuses on my strengths or positive characteristics” (Krueger & Killham, 2005).

Celebrating engaged and productive employees in every organizational role builds upon a basic principle of *operant conditioning*: To teach a behavior, catch a person doing something right and reinforce it. It sounds simple, but many managers are like parents who, when a child brings home near-perfect exam scores, focus on the one low score in a troublesome biology class and ignore the rest. “Sixty-five percent of Americans received NO praise or recognition in the workplace last year,” reported the Gallup Organization (2004).

The bottom line: In the workplace, great managers support employees’ well-being. By caring about their employees and engaging and affirming their strengths, they support happier, more creative, more productive workers with less absenteeism and turnover (Amabile & Kramer, 2011; De Neve et al., 2013). People less often leave bad companies than bad managers (Busteed, 2012). Moreover, the same principles affect college students’ satisfaction, retention, and future success (Larkin et al., 2013; Ray & Kafka, 2014). Students who feel supported by caring friends and mentors, and engaged in their campus life, tend to persist and ultimately succeed during and after college.

Setting Specific, Challenging Goals

Specific, challenging goals motivate achievement, especially when combined with progress reports (Johnson et al., 2006; Latham & Locke, 2007). Specific, measurable objectives, such as “finish gathering the history paper information by Friday,” serve to direct attention, promote effort, motivate persistence, and stimulate creative strategies.

When people state goals together with *subgoals* and *implementation intentions*—action plans that specify when, where, and how they will march toward achieving those goals—they become more focused in their work, and on-time completion becomes more likely (Burgess et al., 2004; Fishbach et al., 2006; Koestner et al., 2002). Through a task’s ups and downs, people best sustain their mood and motivation when they focus on immediate goals (such as daily study) rather than distant goals (such as a course grade). Better to have one’s nose to the grindstone than one’s eye on the ultimate prize (Houser-Marko & Sheldon, 2008).

Thus, before beginning each new edition of this book, our author-editor-staff team *manages by objectives*—we agree on target dates for the completion and editing of each draft. If we focus on achieving each of these short-term goals, the prize—an on-time book—takes care of itself. So, to motivate high productivity, effective leaders work with people to define explicit goals, subgoals, and implementation plans, and then provide feedback on progress.

Choosing an Appropriate Leadership Style

Leadership varies from a boss-focused directive style to an empowered-worker democratic style in which people cooperate in setting goals and developing strategies. Which works best depends on the situation and the leader. The best leadership style

Scott Eklund/AP Photo

The power of positive coaching

Football coach Pete Carroll, who led the University of Southern California to two national championships and the Seattle Seahawks to a Super Bowl championship, combines positive enthusiasm and fun workouts with “a commitment to a nurturing environment that allows people to be themselves while still being accountable to the team” (Trotter, 2014). “It shows you can win with positivity,” notes Seahawks star defensive player Richard Sherman.

task leadership goal-oriented leadership that sets standards, organizes work, and focuses attention on goals.

social leadership group-oriented leadership that builds teamwork, mediates conflict, and offers support.

“Good leaders don’t ask more than their constituents can give, but they often ask—and get—more than their constituents intended to give or thought it was possible to give.”

John W. Gardner, *Excellence*, 1984

for leading a discussion may not be the best style for leading troops on a charge (Fiedler, 1981). Moreover, different leaders are suited to different styles. Some excel at **task leadership**—setting standards, organizing work, and focusing attention on goals. Being goal-oriented, task leaders are good at keeping a group centered on its mission. Typically, they have a directive style, which can work well if the leader is bright enough to give good orders (Fiedler, 1987).

Other managers, many of whom are women, excel at **social leadership**—explaining decisions, mediating conflicts, and building high-achieving teams (Evans & Dion, 1991; Pfaff et al., 2013). Social leaders often have a democratic style: They delegate authority and welcome team members’ participation. Many experiments show that social leadership and team-building increases morale and productivity (Shuffler et al., 2011, 2013). Subordinates usually felt more satisfied and motivated, and performed better, when they participated in decision making (Cawley et al., 1998; Pereira & Osburn, 2007). Moreover, when members are sensitive to one another and participate equally, groups solve problems with greater “collective intelligence” (Woolley et al., 2010).

Because effective leadership styles vary with the situation and the person, the once-popular *great person theory of leadership*—that all great leaders share certain traits—now seems overstated (Vroom & Jago, 2007; Wielkiewicz & Stelzner, 2005). The same coach may seem great or inferior depending on the strength of the team and its competition. But a leader’s personality does matter (Zaccaro, 2007). Effective leaders tend to be neither extremely assertive (impairing social relationships) or unassertive (limiting task leadership) (Ames, 2008). Effective leaders of laboratory groups, work teams, and large corporations have also been found to exude a *charisma* that blends a goal-based vision, clear communication, and optimism that inspires others to follow (House & Singh, 1987; Shamir et al., 1993).

In one study of 50 Dutch companies, the firms with highest morale had chief executives who most inspired their colleagues “to transcend their own self-interests for the sake of the collective” (de Hoogh et al., 2004). *Transformational leadership* of this kind motivates others to identify with and commit themselves to the group’s mission. Transformational leaders, many of whom are natural extraverts, articulate high standards, inspire people to share their vision, and offer personal attention (Bono & Judge, 2004). The frequent result is more engaged, trusting, and effective workers (Turner et al., 2002). As leaders, women more than men tend to exhibit transformational leadership qualities. Alice Eagly (2007, 2013) believes this helps explain why companies with female top managers have tended to enjoy superior financial results, even after controlling for such variables as company size.

Data compiled from studies in India, Taiwan, and Iran indicating that effective managers—whether in coal mines, banks, or government offices—often exhibit a high degree of *both* task and social leadership (Smith & Tayeb, 1989). As achievement-minded people, effective managers certainly care about how well work is done, yet at the same time they are sensitive to their subordinates' needs. Workers in family-friendly organizations that offer flexible-time hours report feeling greater job satisfaction and loyalty to their employers (Butts et al., 2013; Roehling et al., 2001).

A work environment that satisfies one's need to belong also energizes employees. Employees who enjoy high-quality colleague relationships also engage their work with more vigor (Carmeli et al., 2009). Gallup researchers have asked more than 15 million employees worldwide if they have a “best friend at work.” The 30 percent who do “are *seven times* as likely to be engaged in their jobs” as those who don't, report Tom Rath and James Harter (2010). And, as we noted earlier, positive, engaged employees are a mark of thriving organizations.

Increased employee participation in decision making is part of a management style that has spread from Sweden and Japan to many other locations (Naylor, 1990; Sundstrom et al., 1990). Although managers often think better of work they have directly supervised, studies reveal a *voice effect*: Given a chance to voice their opinion and to be part of a decision-making process, people have responded more positively to the decision (van den Bos & Spruijt, 2002). They also feel more empowered, and are likely, therefore, to be more creative and committed (Hennessey & Amabile, 2010; Seibert et al., 2011).

The ultimate in employee participation is the employee-owned company. One such company in my town, the Fleetwood Group, is a 165-employee manufacturer of educational furniture and wireless electronic clickers. When its founder gave 45 percent of the company to his employees, who later bought out other family stockholders, Fleetwood became one of America's first companies with an employee stock ownership plan (ESOP). Today, every employee owns part of the company, and as a group they own 100 percent. The more years employees work, the more they own, yet no one owns more than 5 percent. Like every corporate president, Doug Ruch works for his stockholders—who also just happen to be his employees.

As a company that endorses faith-inspired “servant leadership” and “respect and care for each team member-owner,” Fleetwood is free to place people above profits. Thus, when orders lagged during a recession, the employee-owners decided that job security meant more to them than profits. So the company paid otherwise idle workers to do community service—answering phones at nonprofit agencies, building Habitat for Humanity houses, and the like.

Fleetwood employees “act like they own the place,” notes Ruch. Employee ownership attracts and retains talented people, “drives dedication,” and gives Fleetwood “a sustainable competitive advantage,” he contends. With stock growth averaging 17 percent a year, Fleetwood was named the 2006 National ESOP of the year.

* * *

We have considered *personnel psychology* (the I/O subfield that focuses on employee selection, placement, appraisal, and development). And we have considered *organizational psychology* (the I/O subfield that focuses on worker satisfaction and productivity, and on organizational change). Finally, we turn to *human factors psychology*, which explores the human-machine interface.

RETRIEVAL PRACTICE

- What characteristics are important for *transformational leaders*?

ANSWER: Transformational leaders are able to inspire others to share a vision and commit themselves to a group's mission. They tend to be naturally extraverted and set high standards.

The Human Factor

A-5 How do human factors psychologists work to create user-friendly machines and work settings?

Designs sometimes neglect the human factor. Psychologist Donald Norman bemoaned the complexity of assembling his new HDTV, related components, and seven remotes into a usable home theater system: “I was VP of Advanced Technology at Apple. I can program dozens of computers in dozens of languages. I understand television, really, I do. . . . It doesn’t matter: I am overwhelmed.”

How much easier life might be if engineers would routinely test their designs and instructions on real people. *Human factors psychologists* work with designers and engineers to tailor appliances, machines, and work settings to our natural perceptions and inclinations. Bank ATM machines are internally more complex than remote controls ever were, yet, thanks to human factors engineering, ATMs are easier to operate. Digital recorders have solved the TV recording problem with a simple select-and-click menu system (“record that one”). Apple has similarly engineered easy usability with the iPhone and iPad.

Norman (2001) hosts a website (www.jnd.org) that illustrates good designs that fit people (**FIGURE A.4**). Human factors psychologists also help design efficient environments. An ideal kitchen layout, researchers have found, puts needed items close to their usage point and near eye level. It locates work areas to enable doing tasks in order, such as placing the refrigerator, stove, and sink in a triangle. It creates counters that enable hands to work at or slightly below elbow height (Boehm-Davis, 2005).

Understanding human factors can help prevent accidents. By studying the human factor in driving accidents, psychologists seek to devise ways to reduce the distractions, fatigue, and inattention that contribute to 1.3 million annual worldwide traffic fatalities (Lee, 2008). Two-thirds of commercial air accidents have been caused by human error (Nickerson, 1998). After beginning commercial flights in the 1960s, the Boeing 727 was involved in several landing accidents caused by pilot error. Psychologist Conrad Kraft (1978) noted a common setting for these accidents: All took place at night, and all involved landing short of the runway after crossing a dark stretch of water or unilluminated ground. Kraft reasoned that, on rising terrain, city lights beyond the runway would project a larger retinal image, making the ground seem farther away than it was. By re-creating these conditions in flight simulations, Kraft discovered that pilots were deceived into thinking they were flying higher than their actual altitudes

OXO Good Grips

▼ FIGURE A.4

Designing products that fit people

Human factors psychologist Donald Norman offers these and other examples of effectively designed products.

The Ride On Carry On foldable chair attachment, “designed by a flight attendant mom,” enables a small suitcase to double as a stroller.

The Oxo measuring cup allows the user to see the quantity from above.

(FIGURE A.5). Aided by Kraft's finding, the airlines began requiring the copilot to monitor the altimeter—calling out altitudes during the descent—and the accidents diminished.

Later Boeing psychologists worked on other human factors problems (Murray, 1998): How should airlines best train and manage mechanics to reduce the maintenance errors that underlie about 50 percent of flight delays and 15 percent of accidents? What illumination and typeface would make on-screen flight data easiest to read? How could warning messages be most effectively worded—as an action statement (“Pull Up”) rather than a problem statement (“Ground Proximity”)?

Consider, finally, the available *assistive listening* technologies in various theaters, auditoriums, and places of worship. One technology, commonly available in the United States, requires a headset attached to a pocket-sized receiver that detects infrared or FM signals from the room's sound system. The well-meaning people who design, purchase, and install these systems correctly understand that the technology puts sound directly into the user's ears. Alas, few people with hearing loss undergo the hassle and embarrassment of locating, requesting, wearing, and returning a conspicuous headset. Most such units therefore sit in closets. Britain, the Scandinavian countries, and Australia, and now parts of the United States, have instead installed *loop systems* (see www.hearingloop.org) that broadcast customized sound directly through a person's own hearing aid. When suitably equipped, a hearing aid can be transformed by a discrete touch of a switch into an in-the-ear loudspeaker. Offered convenient, inconspicuous, personalized sound, many more people elect to use assistive listening.

Designs that enable safe, easy, and effective interactions between people and technology often seem obvious after the fact. Why, then, aren't they more common? Technology developers sometimes mistakenly assume that others share their expertise—that what's clear to them will similarly be clear to others (Camerer et al., 1989; Nickerson, 1999). When people rap their knuckles on a table to convey a familiar tune (try this with a friend), they often expect their listener to recognize it. But for the listener, this is a near-impossible task (Newton, 1991). When you know a thing, it's hard to mentally simulate what it's like not to know, and that is called the *curse of knowledge*.

The point to remember: Everyone benefits when designers and engineers tailor machines and environments to fit human abilities and behaviors, when they user-test their inventions before production and distribution, and when they remain mindful of the curse of knowledge.

RETRIEVAL PRACTICE

- What are the three main divisions within industrial-organizational psychology?

ANSWER: personnel, organizational, human factors

▼ FIGURE A.5

The human factor in accidents

Lacking distance cues when approaching a runway from over a dark surface, pilots simulating a night landing tended to fly too low. (Data from Kraft, 1978.)

Steven Day/AP Photo

The human factor in safe landings

Advanced cockpit design and rehearsed emergency procedures aided pilot Chesley “Sully” Sullenberger, a U.S. Air Force Academy graduate who studied psychology and human factors. In January 2009, Sullenberger's instantaneous decisions safely guided his disabled airplane onto New York City's Hudson River, where all 155 of the passengers and crew were safely evacuated.

REVIEW Psychology at Work**LEARNING OBJECTIVES**

RETRIEVAL PRACTICE Take a moment to answer each of these Learning Objective Questions (repeated here from within this appendix). Then turn to Appendix C to check your answers. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009).

A-1 What is *flow*, and what are the three subfields of industrial-organizational psychology?

A-2 How do personnel psychologists help organizations with employee selection, work placement, and performance appraisal?

A-3 What is the role of organizational psychologists?

A-4 What are some effective leadership techniques?

A-5 How do human factors psychologists work to create user-friendly machines and work settings?

Use  **LearningCurve** to create your personalized study plan, which will direct you to the resources that will help you most in  **LaunchPad**.

TERMS AND CONCEPTS TO REMEMBER

RETRIEVAL PRACTICE Test yourself on these terms by trying to write down the definition.

flow, p. A-1

industrial-organizational (I/O) psychology, p. A-2

personnel psychology, p. A-2

organizational psychology, p. A-2

human factors psychology, p. A-2

structured interviews, p. A-6

task leadership, p. A-12

social leadership, p. A-12

TEST YOURSELF**PSYCHOLOGY AT WORK**

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

1. People who view their work as a calling often experience _____, a focused state of consciousness, with diminished awareness of themselves and of time.
 - a. stress
 - b. apathy
 - c. flow
 - d. facilitation
2. _____ psychologists study the recruitment, selection, placement, training, appraisal, and development of employees; _____ psychologists focus on how people and machines interact, and on optimizing devices and work environments.

Personnel Psychology

3. A personnel psychologist scripted a set of questions to ask all applicants for a job opening. She then trained the firm's interviewers to ask only these questions, to take notes, and to rate applicants' responses. This technique is known as a(n)
 - a. structured interview.
 - b. unstructured interview.
 - c. performance appraisal checklist.
 - d. behavior rating scale.

4. In your job, you rate your own performance, your manager's, and your peers'. Your manager, your peers, and your customers also rate your performance. Your organization is using a form of performance appraisal called
 - a. flow procedure.
 - b. graphic feedback.
 - c. structured interviews.
 - d. 360-degree feedback.

Organizational Psychology

5. What type of goals will best help you stay focused and motivated to do your best work in this class?
6. Research indicates that women are more likely than men to have a _____ leadership style.
7. Effective managers often exhibit
 - a. only task leadership.
 - b. only social leadership.
 - c. both task and social leadership, depending on the situation and the person.
 - d. task leadership for building teams and social leadership for setting standards.

 The Human Factor

8. To reduce users' frustration and to avoid accidents, human factors psychologists help organizations avoid the curse of knowledge, which is the tendency for
- a. a little bit of knowledge to be dangerous for the user.
 - b. users to override machines and resort to familiar habits.
 - c. engineers and designers to assume that users are idiots and need overly detailed instructions.
 - d. engineers and designers to assume that others will share their knowledge.

Find answers to these questions in Appendix D.

Subfields of Psychology

Jennifer Zwolinski
University of San Diego

What can you do with a degree in psychology? Lots!

As a psychology major, you will graduate with a scientific mind-set and an awareness of basic principles of human behavior (biological mechanisms, development, cognition, psychological disorders, social interaction). This background will prepare you for success in many areas, including business, the helping professions, health services, marketing, law, sales, and teaching. You may even go on to graduate school for specialized training to become a psychology professional. This appendix describes psychology's specialized subfields.¹ I also provide updated information about CAREERS IN PSYCHOLOGY at www.macmillanhighered.com/launchpad/myers11einmodules, where you can learn more about the many interesting options available to those with bachelor's, master's, and doctoral degrees in psychology.

If you are like most psychology students, you may be unaware of the wide variety of specialties and work settings available in psychology (Terre & Stoddart, 2000). To date, the American Psychological Association (APA) has 56 divisions (TABLE B.1 on the next page). Use social media to learn more about the divisions by visiting www.tinyurl.com/APA-SocialMedia.

The following paragraphs (arranged alphabetically) describe some careers in the main specialty areas of psychology, most of which require a graduate degree in psychology.

Clinical psychologists promote psychological health in individuals, groups, and organizations. Some clinical psychologists specialize in specific psychological disorders. Others treat a range of disorders, from adjustment difficulties to severe psychopathology. Clinical psychologists might engage in research, teaching, assessment, and consultation. Some hold workshops and lectures on psychological issues for other professionals or for the public. Clinical psychologists work in a variety of settings, including private practice, mental health service organizations, schools, universities, industries, legal systems, medical systems, counseling centers, government agencies, and military services.

To become a clinical psychologist, you will need to earn a doctorate from a clinical psychology program. The APA sets the standards for clinical psychology graduate programs, offering accreditation (official recognition) to those who meet their standards. In all U.S. states, clinical psychologists working in independent practice must obtain a license to offer services such as therapy and testing.

Cognitive psychologists study thought processes and focus on such topics as perception, language, attention, problem solving, memory, judgment and decision making, forgetting, and

Cognitive consulting Cognitive psychologists may advise businesses on how to operate more effectively by understanding the human factors involved.

1. Although this text covers the world of psychology for students in many countries, this appendix draws primarily from available U.S. data. Its descriptions of psychology's subfields are, however, also applicable in many other countries.

intelligence. Research interests include designing computer-based models of thought processes and identifying biological correlates of cognition. As a cognitive psychologist, you might work as a professor, industrial consultant, or human factors specialist in an educational or business setting.

Community psychologists move beyond focusing on specific individuals or families and deal with broad problems of mental health in community settings. These psychologists believe that human behavior is powerfully influenced by the interaction between people and their physical, social, political, and economic environments. They seek to promote psychological health by enhancing environmental settings, focusing on preventive measures and crisis intervention, with special attention to the problems of underserved groups and ethnic minorities. Given the shared emphasis on prevention, some community psychologists collaborate with professionals in other areas, such as public health. As a community psychologist, your work settings could include federal, state, and local departments of mental health, corrections, and welfare. You might conduct research or help evaluate research in health service settings, serve as an independent consultant for a private or government agency, or teach and consult as a college or university faculty member.

Counseling psychologists help people adjust to life transitions or make lifestyle changes. Although similar to clinical psychologists, counseling psychologists typically help people with adjustment problems rather than severe psychopathology. Like clinical psychologists, counseling psychologists conduct therapy and provide assessments to individuals and groups. As a counseling psychologist, you would emphasize your clients' strengths, helping them to use their own skills, interests, and abilities to cope during transitions. You might find yourself working in an academic setting as a faculty member or administrator or in a university counseling center, community mental health center, business, or private practice. As with clinical psychology, if you plan to work in independent practice you will need to obtain a state license to provide counseling services to the public.

Developmental psychologists conduct research in age-related behavioral changes and apply their scientific knowledge to educational, child-care, policy, and related settings. As a developmental psychologist, you would investigate change across a broad range of topics, including the biological, psychological, cognitive, and social aspects of development. Developmental psychology informs a number of applied fields, including educational psychology, school psychology, child psychopathology, and gerontology. The field also informs public policy in areas such as education and child-care reform, maternal and child health, and attachment and adoption. You would probably specialize in a specific stage of the life span, such as infancy, childhood, adolescence, or middle or late adulthood. Your work setting could be an educational institution, day-care center, youth group program, or senior center.

Educational psychologists are interested in the psychological processes involved in learning. They study the relationship between learning and the physical and social environments, and they develop strategies for enhancing the learning process. As an educational psychologist, working in a university psychology department or school of education, you might conduct basic research on topics related to learning, or develop innovative methods of teaching to enhance the learning process. You might design effective tests, including measures of aptitude and achievement. You might be employed by a school or government agency or charged with designing and implementing effective employee-training programs in a business setting.

Experimental psychologists are a diverse group of scientists who investigate a variety of basic behavioral processes in humans and other animals. Prominent areas of experimental research include comparative methods of science, motivation, learning,

Community care This community psychologist (left) helped residents work through the emotional challenges that followed the devastating 2010 earthquake in Haiti.

thought, attention, memory, perception, and language. Most experimental psychologists identify with a particular subfield, such as cognitive psychology, depending on their interests and training. It is important to note that experimental research methods are not limited to the field of experimental psychology; many other subfields rely on experimental methodology to conduct studies. As an experimental psychologist, you would most likely work in an academic setting, teaching courses and supervising students' research in addition to conducting your own research. Or you might be employed by a research institution, zoo, business, or government agency.

Forensic psychologists apply psychological principles to legal issues. They conduct research on the interface of law and psychology, help to create public policies related to mental health, help law-enforcement agencies in criminal investigations, or consult on jury selection and deliberation processes. They also provide assessment to assist the legal community. Although most forensic psychologists are clinical psychologists, they might have expertise in other areas of psychology, such as social or cognitive psychology. Some also hold law degrees. As a forensic psychologist, you might work in a university psychology department, law school, research organization, community mental health agency, law-enforcement agency, court, or correctional setting.

Health psychologists are researchers and practitioners concerned with psychology's contribution to promoting health and preventing disease. As applied psychologists or clinicians, they may help individuals lead healthier lives by designing, conducting, and evaluating programs to stop smoking, lose weight, improve sleep, manage pain, prevent the spread of sexually transmitted infections, or treat psychosocial problems associated with chronic and terminal illnesses. As researchers and clinicians, they identify conditions and practices associated with health and illness to help create effective interventions. In public service, health psychologists study and work to improve government policies and health care systems. As a health psychologist, you could be employed in a hospital, medical school, rehabilitation center, public health agency, college or university, or, if you are also a clinical psychologist, in private practice.

Industrial-organizational (I/O) psychologists study the relationship between people and their working environments. They may develop new ways to increase productivity, improve personnel selection, or promote job satisfaction in an organizational setting. Their interests include organizational structure and change, consumer behavior, and personnel selection and training. As an I/O psychologist, you might conduct workplace training or provide organizational analysis and development. You may find yourself working in business, industry, the government, or a college or university. Or you may be self-employed as a consultant or work for a management consulting firm.

Neuropsychologists investigate the relationship between neurological processes (structure and function of the brain) and behavior. As a neuropsychologist you might assess, diagnose, or treat central nervous system disorders, such as Alzheimer's disease or stroke. You might also evaluate individuals for evidence of head injuries; learning and developmental disabilities, such as autism; and other psychiatric disorders, such as attention-deficit hyperactivity disorder (ADHD). If you are a *clinical neuropsychologist*, you might work in a hospital's neurology, neurosurgery, or psychiatric unit. Neuropsychologists also work in academic settings, where they conduct research and teach.

Psychometric and quantitative psychologists study the methods and techniques used to acquire psychological knowledge. A psychometrician may update existing neurocognitive or personality tests or devise new tests for use in clinical and

Criminal investigation Forensic psychologists may be called on to assist police officers investigating a crime scene, as seen here after a shooting in Florida. Most forensic work, however, occurs in the lab and for the judicial system.

school settings or in business and industry. These psychologists also administer, score, and interpret such tests. Quantitative psychologists collaborate with researchers to design, analyze, and interpret the results of research programs. As a psychometric or quantitative psychologist, you will need to be well trained in research methods, statistics, and computer technology. You will most likely be employed by a university or college, testing company, private research firm, or government agency.

Rehabilitation psychologists are researchers and practitioners who work with people who have lost optimal functioning after an accident, illness, or other event. As a rehabilitation psychologist, you would probably work in a medical rehabilitation institution or hospital. You might also work in a medical school, university, state or federal vocational rehabilitation agency, or in private practice serving people with physical disabilities.

School psychologists are involved in the assessment of and intervention for children in educational settings. They diagnose and treat cognitive, social, and emotional problems that may negatively influence children's learning or overall functioning at school. As a school psychologist, you would collaborate with teachers, parents, and administrators, making recommendations to improve student learning. You would work in an academic setting, a federal or state government agency, a child guidance center, or a behavioral research laboratory.

Social psychologists are interested in our interactions with others. Social psychologists study how our beliefs, feelings, and behaviors are affected by and influence other people. They study topics such as attitudes, aggression, prejudice, interpersonal attraction, group behavior, and leadership. As a social psychologist, you would probably be a college or university faculty member. You might also work in organizational consultation, market research, or other applied psychology fields, including social neuroscience. Some social psychologists work for hospitals, federal agencies, or businesses performing applied research.

Sport psychologists study the psychological factors that influence, and are influenced by, participation in sports and other physical activities. Their professional activities include coach education and athlete preparation, as well as research and teaching. Sport psychologists who also have a clinical or counseling degree can apply those skills to working with individuals with psychological problems, such as anxiety or substance abuse, that might interfere with optimal performance. As a sport psychologist, if you were not working in an academic or research setting, you would most likely work as part of a team or an organization or in a private capacity.

* * *

So, the next time someone asks you what you will do with your psychology degree, tell them you have a lot of options. You might use your acquired skills and understanding to get a job and succeed in any number of fields, or you might pursue graduate school and then career opportunities in associated professions. In any case, what you have learned about behavior and mental processes will surely enrich your life (Hammer, 2003).

PROLOGUE

THE STORY OF PSYCHOLOGY

What Is Psychology?

P-1 What were some important milestones in psychology's early development?

Wilhelm Wundt established the first psychological laboratory in 1879 in Germany. Two early schools were *structuralism* and *functionalism*.

P-2 How did psychology continue to develop from the 1920s through today?

Early researchers defined *psychology* as “the science of mental life.” In the 1920s, under the influence of John B. Watson and the *behaviorists*, the field's focus changed to the “scientific study of observable behavior.” In the 1960s, the *humanistic psychologists* and the *cognitive psychologists* revived interest in the study of mental processes. Psychology is now defined as the science of behavior and mental processes.

P-3 How has our understanding of biology and experience, culture and gender, and human flourishing shaped contemporary psychology?

Our growing understanding of biology and experience has fed psychology's most enduring debate. The *nature–nurture issue* centers on the relative contributions of genes and experience, and their interaction in specific environments. Charles Darwin's view that *natural selection* shapes behaviors as well as bodies led to *evolutionary psychology's* study of our similarities because of our common biology and evolutionary history, and *behavior genetics'* focus on the relative power and limits of genetic and environmental influences on behavior.

Cross-cultural and gender studies have diversified psychology's assumptions while also reminding us of our similarities. Attitudes and behaviors may vary somewhat by gender or across *cultures*, but because of our shared human kinship, the underlying processes and principles are more similar than different.

Psychology's traditional focus on understanding and treating troubles has expanded with *positive psychology's* call for more research on human flourishing and its attempt to discover and promote traits that help people to thrive.

P-4 What are psychology's levels of analysis and related perspectives?

The *biopsychosocial approach* integrates information from three differing but complementary *levels of analysis*: the biological, psychological, and social-cultural. This approach offers a more complete understanding than could usually be reached by relying on only one of psychology's current perspectives (neuroscience, evolutionary, behavior genetics, psychodynamic, behavioral, cognitive, and social-cultural).

P-5 What are psychology's main subfields?

Within the science of psychology, researchers may conduct *basic research* to increase the field's knowledge base (often in biological, developmental, cognitive, personality, and social psychology) or *applied research* to solve practical problems (in industrial-organizational psychology and other areas).

Those who engage in psychology as a helping profession may assist people as *counseling psychologists*, helping people with problems in living or achieving greater well-being, or as *clinical psychologists*, studying and assessing people with psychological disorders and treating them with psychotherapy. (*Psychiatrists* also study, assess, and treat people with disorders, but as medical doctors, they may prescribe drugs in addition to psychotherapy.) *Community psychologists* work to create healthy social and physical environments (in schools, for example).

P-6 How can psychological principles help you learn and remember?

The *testing effect* shows that learning and memory are enhanced by actively retrieving, rather than simply rereading, previously studied material. The SQ3R study method—survey, question, read, retrieve, and review—applies principles derived from memory research. Four additional tips are (1) distribute your study time; (2) learn to think critically; (3) process class information actively; and (4) overlearn.

CHAPTER 1

THINKING CRITICALLY WITH PSYCHOLOGICAL SCIENCE

The Need for Psychological Science

1-1 How does our everyday thinking sometimes lead us to a wrong conclusion?

Our everyday thinking can be perilous because of three phenomena: hindsight bias, overconfidence, and a tendency to perceive patterns in random events. *Hindsight bias* (also called the “I-knew-it-all-along phenomenon”) is the tendency to believe, after learning an outcome, that we would have foreseen it. Overconfidence in our judgments results partly from our bias to seek information that confirms them. These tendencies, plus our eagerness to perceive patterns in random events, lead us to overestimate our *intuition*. Although limited by the testable questions it can address, scientific inquiry can help us overcome our intuition’s biases and shortcomings.

1-2 How do the scientific attitude’s three main components relate to critical thinking?

The scientific attitude equips us to be curious, skeptical, and humble in scrutinizing competing ideas or our own observations. This attitude carries into everyday life as *critical thinking*, which puts ideas to the test by examining assumptions, appraising the source, discerning hidden values, evaluating evidence, and assessing conclusions.

Research Strategies: How Psychologists Ask and Answer Questions

1-3 How do theories advance psychological science?

Psychological *theories* are explanations that apply an integrated set of principles to organize observations and generate *hypotheses*—predictions that can be used to check the theory or produce practical applications of it. By testing their hypotheses, researchers can confirm, reject, or revise their theories. To enable other researchers to *replicate* the studies, researchers report them using precise *operational definitions* of their procedures and concepts. If others achieve similar results, confidence in the conclusion will be greater.

1-4 How do psychologists use case studies, naturalistic observations, and surveys to observe and describe behavior, and why is random sampling important?

Descriptive methods, which include *case studies*, *naturalistic observations*, and *surveys*, show us what can happen, and they may offer ideas for further study. The best basis for

generalizing about a *population* is a representative sample; in a *random sample*, every person in the entire population being studied has an equal chance of participating. Descriptive methods cannot show cause and effect because researchers cannot control variables.

1-5 What does it mean when we say two things are correlated, and what are positive and negative correlations?

When we say two things are correlated, we are saying that they accompany each other in their movements. In a positive *correlation*, two factors increase or decrease together. In a negative correlation, one item increases as the other decreases. The strength of their relationship is expressed as a *correlation coefficient*, which ranges from +1.00 (a perfect positive correlation) through 0 (no correlation) to -1.00 (a perfect negative correlation). Their relationship may be displayed in a *scatterplot*, in which each dot represents a value for the two variables.

1-6 What is regression toward the mean?

Regression toward the mean is the tendency for extreme or unusual scores to fall back toward their average.

1-7 Why do correlations enable prediction but not cause-effect explanation?

Correlations enable prediction because they show how two factors move together, either positively or negatively. A correlation can indicate the possibility of a cause-effect relationship, but it does not prove the direction of the influence, or whether an underlying third factor may explain the correlation.

1-8 What are the characteristics of experimentation that make it possible to isolate cause and effect?

To discover cause-effect relationships, psychologists conduct *experiments*, manipulating one or more factors of interest and controlling other factors. Using *random assignment*, they can minimize *confounding variables*, such as preexisting differences between the *experimental group* (exposed to the treatment) and the *control group* (given a placebo or different version of the treatment). The *independent variable* is the factor the experimenter manipulates to study its effect; the *dependent variable* is the factor the experimenter measures to discover any changes occurring in response to the manipulations. Studies may use a *double-blind procedure* to avoid the *placebo effect*.

1-9 Can laboratory experiments illuminate everyday life?

Researchers intentionally create a controlled, artificial environment in the laboratory in order to test general theoretical principles. These general principles help explain everyday behaviors.

1-10 Why do psychologists study animals, and what ethical guidelines safeguard human and animal research participants? How do human values influence psychology?

Some psychologists are primarily interested in animal behavior; others want to better understand the physiological and psychological processes shared by humans and other species. Government agencies have established standards for animal care and housing. Professional associations and funding agencies also establish guidelines for protecting animals' well-being. The APA ethics code outlines standards for safeguarding human participants' well-being, including obtaining their *informed consent* and *debriefing* them later.

Psychologists' values influence their choice of research topics, their theories and observations, their labels for behavior, and their professional advice. Applications of psychology's principles have been used mainly in the service of humanity.

Statistical Reasoning in Everyday Life

1-11 How do we describe data using three measures of central tendency, and what is the relative usefulness of the two measures of variation?

A measure of central tendency is a single score that represents a whole set of scores. Three such measures that we use to describe data are the *mode* (the most frequently occurring score), the *mean* (the arithmetic average), and the *median* (the middle score in a group of data).

Measures of variation tell us how diverse data are. Two measures of variation are the *range* (which describes the gap between the highest and lowest scores) and the *standard deviation* (which states how much scores vary around the mean, or average, score). Scores often form a *normal* (or bell-shaped) *curve*.

1-12 How do we know whether an observed difference can be generalized to other populations?

To feel confident about generalizing an observed difference to other populations, we would want to know that the sample studied was representative of the larger population being studied; that the observations, on average, had low variability; that the sample consisted of more than a few cases; and that the observed difference was *statistically significant*.

CHAPTER 2

THE BIOLOGY OF MIND

Neural and Hormonal Systems

2-1 Why are psychologists concerned with human biology?

Psychologists working from a *biological* perspective study the links between biology and behavior. We are biopsychosocial systems, in which biological, psychological, and social-cultural factors interact to influence behavior.

2-2 What are neurons, and how do they transmit information?

Neurons are the elementary components of the nervous system, the body's speedy electrochemical information system. A neuron receives signals through its branching *dendrites*, and sends signals through its *axons*. Some axons are encased in a *myelin sheath*, which enables faster transmission. *Glial cells* provide myelin, and they support, nourish, and protect neurons; they may also play a role in learning and thinking.

If the combined signals received by a neuron exceed a minimum *threshold*, the neuron fires, transmitting an electrical impulse (the *action potential*) down its axon by means of a chemistry-to-electricity process. The neuron's reaction is an *all-or-none process*.

2-3 How do nerve cells communicate with other nerve cells?

When action potentials reach the end of an axon (the axon terminals), they stimulate the release of *neurotransmitters*. These chemical messengers carry a message from the sending neuron across a *synapse* to receptor sites on a receiving neuron. The sending neuron, in a process called *reuptake*, then normally reabsorbs the excess neurotransmitter molecules in the synaptic gap. If incoming signals are strong enough, the receiving neuron generates its own action potential and relays the message to other cells.

2-4 How do neurotransmitters influence behavior, and how do drugs and other chemicals affect neurotransmission?

Neurotransmitters travel designated pathways in the brain and may influence specific behaviors and emotions. Acetylcholine (ACh) affects muscle action, learning, and memory. *Endorphins* are natural opiates released in response to pain and exercise.

Drugs and other chemicals affect brain chemistry at synapses. *Agonists* increase a neurotransmitter's action, and may do so in various ways. *Antagonists* decrease a neurotransmitter's action by blocking production or release.

2-5 What are the functions of the nervous system's main divisions, and what are the three main types of neurons?

The *central nervous system* (CNS)—the brain and the spinal cord—is the *nervous system's* decision maker. The *peripheral nervous system* (PNS), which connects the CNS to the rest of the body by means of *nerves*, gathers information and transmits CNS decisions to the rest of the body. The two main PNS divisions are the *somatic nervous system* (which enables voluntary control of the skeletal muscles) and the *autonomic nervous system* (which controls involuntary muscles and glands by means of its *sympathetic* and *parasympathetic* divisions).

Neurons cluster into working networks. There are three types of neurons: (1) *Sensory (afferent) neurons* carry incoming information from sensory receptors to the brain and spinal cord. (2) *Motor (efferent) neurons* carry information from the brain and spinal cord out to the muscles and glands. (3) *Interneurons* communicate within the brain and spinal cord and between sensory and motor neurons.

2-6 How does the endocrine system transmit information and interact with the nervous system?

The *endocrine system* is a set of glands that secrete *hormones* into the bloodstream, where they travel through the body and affect other tissues, including the brain. The endocrine system's master gland, the *pituitary*, influences hormone release by other glands, including the *adrenal glands*. In an intricate feedback system, the brain's hypothalamus influences the pituitary gland, which influences other glands, which release hormones, which in turn influence the brain.

Tools of Discovery and Older Brain Structures

2-7 How do neuroscientists study the brain's connections to behavior and mind?

Clinical observations and *lesioning* reveal the general effects of brain damage. Electrical, chemical, or magnetic stimulation can also reveal aspects of information processing in the brain. *MRI* scans show anatomy. *EEG*, *PET*, and *fMRI* (*functional MRI*) recordings reveal brain function.

2-8 What structures make up the brainstem, and what are the functions of the brainstem, thalamus, reticular formation, and cerebellum?

The *brainstem*, the oldest part of the brain, is responsible for automatic survival functions. Its components are the *medulla* (which controls heartbeat and breathing), the *pons* (which helps coordinate movements), and the *reticular formation* (which affects arousal).

The *thalamus*, sitting above the brainstem, acts as the brain's sensory control center. The *cerebellum*, attached to the rear of the brainstem, coordinates muscle movement and balance and also helps process sensory information.

2-9 What are the limbic system's structures and functions?

The *limbic system* is linked to emotions, memory, and drives. Its neural centers include the *hippocampus* (which processes conscious memories); the *amygdala* (involved in responses of aggression and fear); and the *hypothalamus* (involved in various bodily maintenance functions, pleasurable rewards, and the control of the endocrine system). The hypothalamus controls the pituitary (the "master gland") by stimulating it to trigger the release of hormones.

The Cerebral Cortex and Our Divided Brain

2-10 What are the functions of the various cerebral cortex regions?

The *cerebral cortex* has two hemispheres, and each hemisphere has four lobes: the *frontal*, *parietal*, *occipital*, and *temporal*. Each lobe performs many functions and interacts with other areas of the cortex.

The *motor cortex*, at the rear of the frontal lobes, controls voluntary movements. The *somatosensory cortex*, at the front of the parietal lobes, registers and processes body touch and movement sensations. Body parts requiring precise control (in the motor cortex) or those that are especially sensitive (in the somatosensory cortex) occupy the greatest amount of space.

Most of the brain's cortex—the major portion of each of the four lobes—is devoted to uncommitted *association areas*, which integrate information involved in learning, remembering, thinking, and other higher-level functions. Our mental experiences arise from coordinated brain activity.

2-11 To what extent can a damaged brain reorganize itself, and what is neurogenesis?

If one hemisphere is damaged early in life, the other will pick up many of its functions by reorganizing or building new pathways. This *plasticity* diminishes later in life. The brain sometimes mends itself by forming new neurons, a process known as *neurogenesis*.

2-12 What do split brains reveal about the functions of our two brain hemispheres?

Split-brain research (experiments on people with a severed *corpus callosum*) has confirmed that in most people, the left hemisphere is the more verbal, and that the right hemisphere excels in visual perception and the recognition of emotion. Studies of healthy people with intact brains confirm that each hemisphere makes unique contributions to the integrated functioning of the brain.

2-13 What does research tell us about being left-handed? Is it advantageous to be right-handed?

Some 10 percent of us (somewhat more among males, somewhat less among females) are left-handed. Handedness appears to be influenced by genetic or prenatal factors. Most left-handers process speech in the left hemisphere, as right-handers do, but some do so in the right hemisphere or use both hemispheres. Left-handers are more likely to be among those with reading disabilities, allergies, and migraine headaches, but sometimes do better academically. Left-handedness is also more common among musicians, mathematicians, architects, artists, and in professional baseball and cricket players. The pros and cons of being left-handed seem roughly equal.

CHAPTER 3

CONSCIOUSNESS AND THE TWO-TRACK MIND

Brain States and Consciousness

3-1 What is the place of consciousness in psychology's history?

Since 1960, under the influence of cognitive psychology, neuroscience, and *cognitive neuroscience*, our awareness of ourselves and our environment—our *consciousness*—has reclaimed its place as an important area of research. After initially claiming consciousness as its area of study in the nineteenth century, psychologists had abandoned it in the first half of the twentieth century, turning instead to the study of observable behavior because they believed consciousness was too difficult to study scientifically.

3-2 What is the “dual processing” being revealed by today’s cognitive neuroscience?

Scientists studying the brain mechanisms underlying consciousness and cognition have discovered that the mind processes information on two separate tracks, one operating at an explicit, conscious level (conscious sequential processing) and the other at an implicit, unconscious level (unconscious parallel processing). This *dual processing* affects our perception, memory, attitudes, and other cognitions.

3-3 How does selective attention direct our perceptions?

We *selectively attend* to, and process, a very limited portion of incoming information, blocking out much and often shifting the spotlight of our attention from one thing to another. *Parallel processing* takes care of the routine business, while sequential processing is best for solving new problems that require our attention. Focused intently on one task, we often display *inattentional blindness* to other events and *change blindness* to changes around us.

Sleep and Dreams

3-4 What is sleep?

Sleep is the periodic, natural loss of consciousness—as distinct from unconsciousness resulting from a coma, general anesthesia, or hibernation. (Adapted from Dement, 1999.)

3-5 How do our biological rhythms influence our daily functioning?

Our bodies have an internal biological clock, roughly synchronized with the 24-hour cycle of night and day. This *circadian rhythm* appears in our daily patterns of body temperature, arousal, sleeping, and waking. Age and experiences can alter these patterns, resetting our biological clock.

3-6 What is the biological rhythm of our sleeping and dreaming stages?

Younger adults cycle through four distinct sleep stages about every 90 minutes. (The sleep cycle repeats more frequently for older adults.) Leaving the *alpha waves* of the awake, relaxed stage, we descend into the irregular brain waves of non-REM stage 1 (NREM-1) sleep, often with *hallucinations*, such as the sensation of falling or floating. NREM-2 sleep (in which we spend the most time) follows, lasting about 20 minutes, with its characteristic sleep spindles. We then enter NREM-3 sleep, lasting about 30 minutes, with large, slow *delta waves*.

About an hour after falling asleep, we begin periods of *REM* (rapid eye movement) *sleep*. Most dreaming occurs in this stage (also known as paradoxical sleep) of internal arousal but outward paralysis. During a normal night’s sleep, NREM-3 sleep shortens and REM and NREM-2 sleep lengthens.

3-7 How do biology and environment interact in our sleep patterns?

Our biology—our circadian rhythm as well as our age and our body’s production of melatonin (influenced by the brain’s *suprachiasmatic nucleus*)—interacts with cultural expectations and individual behaviors to determine our sleeping and waking patterns.

3-8 What are sleep’s functions?

Sleep may have played a protective role in human evolution by keeping people safe during potentially dangerous periods. Sleep also helps restore and repair damaged neurons. REM and NREM-2 sleep help strengthen neural connections that build enduring memories. Sleep promotes creative problem solving the next day. Finally, during deep sleep, the pituitary gland secretes a growth hormone necessary for muscle development.

3-9 How does sleep loss affect us, and what are the major sleep disorders?

Sleep deprivation causes fatigue and irritability, and it impairs concentration, productivity, and memory consolidation. It can also lead to depression, obesity, joint pain, a suppressed immune system, and slowed performance (with greater vulnerability to accidents).

Sleep disorders include *insomnia* (recurring wakefulness); *narcolepsy* (sudden uncontrollable sleepiness or lapsing into REM sleep); *sleep apnea* (the stopping of breathing while asleep; associated with obesity, especially in men); *night terrors* (high arousal and the appearance of being terrified; NREM-3 disorder found mainly in children); sleepwalking (NREM-3 disorder also found mainly in children); and sleepwalking.

3-10 What do we dream?

We usually *dream* of ordinary events and everyday experiences, most involving some anxiety or misfortune. Fewer than 10 percent of dreams among men (and less among women) have any sexual content. Most dreams occur during REM sleep.

3-11 What functions have theorists proposed for dreams?

There are five major views of the function of dreams. (1) Freud's wish-fulfillment: Dreams provide a psychic "safety valve," with *manifest content* (story line) acting as a censored version of *latent content* (underlying meaning that gratifies our unconscious wishes). (2) Information-processing: Dreams help us sort out the day's events and consolidate them in memory. (3) Physiological function: Regular brain stimulation may help develop and preserve neural pathways in the brain. (4) Neural activation: The brain attempts to make sense of neural static by weaving it into a story line. (5) Cognitive development: Dreams reflect the dreamer's level of development.

Most sleep theorists agree that REM sleep and its associated dreams serve an important function, as shown by the *REM rebound* that occurs following REM deprivation in humans and other species.

Drugs and Consciousness

3-12 What are substance use disorders, and what roles do tolerance, withdrawal, and addiction play in these disorders?

Those with a *substance use disorder* may exhibit impaired control, social disruption, risky behavior, and the physical effects of tolerance and withdrawal. *Psychoactive drugs* alter perceptions and moods. They may produce *tolerance*—requiring larger doses to achieve the desired effect—and *withdrawal*—significant discomfort accompanying attempts to quit. Continued use may lead to *addiction*, which is the compulsive craving of drugs or certain behaviors (such as gambling) despite known adverse consequences.

3-13 How has the concept of addiction changed?

Psychologists debate whether the concept of addiction has been stretched too far, and whether addictions are really as irresistible as commonly believed. Addictions can be powerful, and many with addictions do benefit from therapy or group support. But viewing addiction as an uncontrollable disease can undermine people's self-confidence and their belief that they can change. The addiction-as-disease-needing-treatment idea has been extended to a host of excessive, driven behaviors, but labeling a behavior doesn't explain it. The concept of addiction continues to evolve, as psychiatry's manual of disorders now includes behavior addictions such as "gambling disorder" and proposes "Internet gaming disorder" for further study.

3-14 What are depressants, and what are their effects?

Depressants, such as alcohol, *barbiturates*, and the *opiates*, dampen neural activity and slow body functions. Alcohol tends to disinhibit, increasing the likelihood that we will

act on our impulses, whether harmful or helpful. It also impairs judgment, disrupts memory processes by suppressing REM sleep, and reduces self-awareness and self-control. User expectations strongly influence alcohol's behavioral effects.

3-15 What are stimulants, and what are their effects?

Stimulants—including caffeine, nicotine, cocaine, the amphetamines, methamphetamine, and Ecstasy—excite neural activity and speed up body functions, triggering energy and mood changes. All are highly addictive. Nicotine's effects make smoking a difficult habit to kick, yet the percentage of Americans who smoke has been dramatically decreasing. Cocaine gives users a fast high, followed within an hour by a crash. Its risks include cardiovascular stress and suspiciousness. Use of methamphetamines may permanently reduce dopamine production. Ecstasy (MDMA) is a combined stimulant and mild hallucinogen that produces euphoria and feelings of intimacy. Its users risk immune system suppression, permanent damage to mood and memory, and (if taken during physical activity) dehydration and escalating body temperatures.

3-16 What are hallucinogens, and what are their effects?

Hallucinogens—such as LSD and marijuana—distort perceptions and evoke hallucinations—sensory images in the absence of sensory input. The user's mood and expectations influence the effects of LSD, but common experiences are hallucinations and emotions varying from euphoria to panic. Marijuana's main ingredient, THC, may trigger feelings of disinhibition, euphoria, relaxation, relief from pain, and intense sensitivity to sensory stimuli. It may also increase feelings of depression or anxiety, impair motor coordination and reaction time, disrupt memory formation, and damage lung tissue (because of the inhaled smoke).

3-17 Why do some people become regular users of consciousness-altering drugs?

Some people may be biologically vulnerable to particular drugs, such as alcohol. Psychological factors (such as stress, depression, and hopelessness) and social factors (such as peer pressure) combine to lead many people to experiment with—and sometimes become addicted to—drugs. Cultural and ethnic groups have differing rates of drug use. Each type of influence—biological, psychological, and social-cultural—offers a possible path for drug misuse prevention and treatment programs.

CHAPTER 4

NATURE, NURTURE, AND HUMAN DIVERSITY

Behavior Genetics: Predicting Individual Differences

4-1 What are chromosomes, DNA, genes, and the human genome? How do behavior geneticists explain our individual differences?

Genes are the biochemical units of heredity that make up *chromosomes*, the thread-like coils of DNA. When genes are “turned on” (expressed), they provide the code for creating the proteins that form our body's building blocks. Most human traits are influenced by many genes acting together. The *human genome* is the shared genetic profile that distinguishes humans from other species, consisting at an individual level of all the genetic material in an organism's chromosomes. *Behavior geneticists* study the relative power and limits of genetic and *environmental* influences on behavior.

4-2 How do twin and adoption studies help us understand the effects and interactions of nature and nurture?

Studies of *identical* (monozygotic) *twins* versus *fraternal* (dizygotic) *twins*, separated twins, and biological versus adoptive relatives allow researchers to tease apart the

influences of heredity and environment. Research studies on separated identical twins maintain the same genes while testing the effects of different home environments. Studies of adoptive families let researchers maintain the same home environment while studying the effects of genetic differences. Heritable individual differences (in traits such as height and weight) do not necessarily explain gender or ethnic group differences. Shared family environments have little effect on personality.

4-3 What have psychologists learned about temperament?

The stability of *temperament*, a person's characteristic emotional reactivity and intensity, from the first weeks of life suggests a genetic predisposition. The genetic effect appears in physiological differences such as heart rate and nervous system reactivity.

4-4 What is *heritability*, and how does it relate to individuals and groups?

Heritability describes the extent to which variation among members of a group can be attributed to genes. Heritable individual differences (in traits such as height or intelligence) need not imply heritable group differences. Genes mostly explain why some people are taller than others, but not why people are taller today than they were a century ago.

4-5 How is molecular genetics research changing our understanding of the effects of nature and nurture?

Molecular genetics research on structure and function of genes is building new understandings of how teams of genes influence many human traits. One goal of *molecular behavior genetics*, the study of how the structure and function of genes interact with our environment to influence behavior, is to find some of the many genes that together orchestrate complex traits (such as body weight, sexual orientation, and impulsivity). Environments can trigger or block genetic expression. The field of *epigenetics* studies the influences on gene expression that occur without changes in DNA.

4-6 What are some benefits and risks of prenatal genetic testing?

Genetic tests can now reveal at-risk populations for dozens of diseases, and the search is on to discover the markers of genetically influenced disorders. But prenatal screening poses ethical dilemmas. For example, testing for an offspring's sex has enabled selective abortions, which in some cultures has resulted in millions more male births. And future screening for vulnerability to psychological disorders could deprive the world of great talents. (Handel, van Gogh, Churchill, Lincoln, Tolstoy, and Dickinson were all troubled people, for example.)

Evolutionary Psychology: Understanding Human Nature

4-7 How do evolutionary psychologists use natural selection to explain behavior tendencies?

Evolutionary psychologists seek to understand how our traits and behavior tendencies are shaped by *natural selection*, as genetic variations increasing the odds of reproducing and surviving in their particular environment are most likely to be passed on to future generations. Some variations arise from *mutations* (random errors in gene replication), others from new gene combinations at conception. Humans share a genetic legacy and are predisposed to behave in ways that promoted our ancestors' surviving and reproducing. Charles Darwin's theory of evolution is an organizing principle in biology. He anticipated today's application of evolutionary principles in psychology.

4-8 How might an evolutionary psychologist explain male-female differences in sexuality and mating preferences?

Men tend to have a recreational view of sexual activity; women tend to have a relational view. Evolutionary psychologists reason that men's attraction to multiple healthy,

fertile-appearing partners increases their chances of spreading their genes widely. Because women incubate and nurse babies, they increase their own and their children's chances of survival by searching for mates with the potential for long-term investment in their joint offspring.

4-9 What are the key criticisms of evolutionary explanations of human sexuality, and how do evolutionary psychologists respond?

Critics argue that evolutionary psychologists start with an effect and work backward to an explanation. They also charge that evolutionary psychologists try to explain today's behavior based on decisions our distant ancestors made thousands of years ago, noting that a better, more immediate explanation takes learned *social scripts* into account. And, the critics wonder, does this kind of explanation absolve people from taking responsibility for their sexual behavior? Evolutionary psychologists respond that understanding our predispositions can help us overcome them. They recognize the importance of social and cultural influences, but they also cite the value of testable predictions based on evolutionary principles.

Culture, Gender, and Other Environmental Influences

4-10 How do early experiences modify the brain?

Our genetic predispositions and our specific environments *interact*. Environments can trigger gene activity, and genetically influenced traits can evoke responses from others.

As a child's brain develops, neural connections grow more numerous and complex. Experiences then prompt a pruning process, in which unused connections weaken and heavily used ones strengthen. Early childhood is an important period for shaping the brain, but throughout our lives our brain modifies itself in response to our learning.

4-11 In what ways do parents and peers shape children's development?

Parents influence their children in areas such as manners and political and religious beliefs, but not in other areas, such as personality. As children attempt to fit in with their peers, they tend to adopt their culture—styles, accents, slang, attitudes. By choosing their children's neighborhoods and schools, parents exert some influence over peer group culture.

4-12 How does culture affect our behavior?

A *culture* is an enduring set of behaviors, ideas, attitudes, values, and traditions shared by a group and transmitted from one generation to the next. Cultural *norms* are understood rules that inform members of a culture about accepted and expected behaviors. Cultures differ across time and space.

4-13 How do individualist and collectivist cultures differ in their values and goals?

Within any culture, the degree of individualism or collectivism varies from person to person. Cultures based on self-reliant *individualism*, like those found in North America and Western Europe, tend to value personal independence and individual achievement. They define identity in terms of self-esteem, personal goals and attributes, and personal rights and liberties. Cultures based on socially connected *collectivism*, like those in many parts of Asia and Africa, tend to value interdependence, tradition, and harmony, and they define identity in terms of group goals, commitments, and belonging to one's group.

4-14 How does the meaning of *gender* differ from the meaning of *sex*?

In psychology, *gender* is the socially influenced characteristics by which people define men and women. *Sex* refers to the biologically influenced characteristics by which

people define males and females. Our gender is thus the product of the interplay among our biological dispositions, our developmental experiences, and our current situation.

4-15 What are some ways in which males and females tend to be alike and to differ?

We are more alike than different, thanks to our similar genetic makeup—we see, hear, learn, and remember similarly. Males and females do differ in body fat, muscle, height, age of onset of puberty, life expectancy, and vulnerability to certain disorders. Men admit to more *aggression* than women do, and they are more likely to be physically aggressive. Women's aggression is more likely to be *relational*. In most societies, men have more social power, and their leadership style tends to be directive, whereas women's is more democratic. Women focus more on social connectedness, and they “tend and befriend.”

4-16 How do sex hormones influence prenatal and adolescent sexual development, and what is a disorder of sexual development?

Both sex chromosomes and sex hormones influence development. Biological sex is determined by the father's contribution to the twenty-third pair of chromosomes. The mother always contributes an X *chromosome*. The father may also contribute an X chromosome, producing a female, or a Y *chromosome*, producing a male by triggering additional *testosterone* release and the development of male sex organs. During *puberty*, both *primary* and *secondary sex characteristics* develop. Sex-related genes and physiology influence behavioral and cognitive differences between males and females. *Disorders of sexual development* are inherited conditions that involve unusual development of sex chromosomes and anatomy.

4-17 How do gender roles and gender identity differ?

Gender roles, the behaviors a culture expects from its males and females, vary across place and time. *Social learning theory* proposes that we learn *gender identity*—our sense of being male, female, or some combination of the two—as we learn other things: through reinforcement, punishment, and observation. Critics argue that cognition also plays a role because modeling and rewards cannot explain *gender typing*. Some children organize themselves into “boy worlds” and “girl worlds”; others prefer *androgyny*. *Trans-gender* people's gender identity or expression differs from their birth sex. Their sexual orientation may be heterosexual, homosexual, bisexual, or asexual.

4-18 What is included in the biopsychosocial approach to development?

Individual development results from the interaction of biological, psychological, and social-cultural influences. Biological influences include our shared human genome; individual variations; prenatal environment; and sex-related genes, hormones, and physiology. Psychological influences include gene-environment interactions; the effect of early experiences on neural networks; responses evoked by our own characteristics, such as gender and temperament; and personal beliefs, feelings, and expectations. Social-cultural influences include parental and peer influences; cultural traditions and values; and cultural gender norms.

CHAPTER 5

DEVELOPING THROUGH THE LIFE SPAN

Developmental Issues, Prenatal Development, and the Newborn

5-1 What three issues have engaged developmental psychologists?

Developmental psychologists study physical, mental, and social changes throughout the life span. They focus on three issues: nature and nurture (the interaction between our

genetic inheritance and our experiences); continuity and stages (whether development is gradual and continuous or a series of relatively abrupt changes); and stability and change (whether our traits endure or change as we age).

5-2 What is the course of prenatal development, and how do teratogens affect that development?

The life cycle begins at conception, when one sperm cell unites with an egg to form a *zygote*. The zygote's inner cells become the *embryo*, and the outer cells become the placenta. In the next 6 weeks, body organs begin to form and function, and by 9 weeks, the *fetus* is recognizably human.

Teratogens are potentially harmful agents that can pass through the placental screen and harm the developing embryo or fetus, as happens with *fetal alcohol syndrome*.

5-3 What are some newborn abilities, and how do researchers explore infants' mental abilities?

Babies are born with sensory equipment and reflexes that facilitate their survival and their social interactions with adults. For example, they quickly learn to discriminate their mother's smell and sound. Researchers use techniques that test *habituation*, such as the novelty-preference procedure, to explore infants' abilities.

Infancy and Childhood

5-4 During infancy and childhood, how do the brain and motor skills develop?

The brain's nerve cells are sculpted by heredity and experience. As a child's brain develops, neural connections grow more numerous and complex. Experiences then trigger a pruning process, in which unused connections weaken and heavily used ones strengthen. This process continues until puberty. Early childhood is an important period for shaping the brain, but our brain modifies itself in response to our learning throughout life. In childhood, complex motor skills—sitting, standing, walking—develop in a predictable sequence, though the timing of that sequence is a function of individual *maturation* and culture. We have no conscious memories of events occurring before about age 3½. This infantile amnesia occurs in part because major brain areas have not yet matured.

5-5 From the perspectives of Piaget, Vygotsky, and today's researchers, how does a child's mind develop?

In his theory of *cognitive* development, Jean Piaget proposed that children actively construct and modify their understanding of the world through the processes of *assimilation* and *accommodation*. They form *schemas* that help them organize their experiences. Progressing from the simplicity of the *sensorimotor stage* of the first two years, in which they develop *object permanence*, children move to more complex ways of thinking. In the *preoperational stage* (about age 2 to about 6 or 7), they develop a *theory of mind*. In the preoperational stage, children are *egocentric* and unable to perform simple logical operations. At about age 7, they enter the *concrete operational stage* and are able to comprehend the principle of *conservation*. By about age 12, children enter the *formal operational stage* and can reason systematically.

Research supports the sequence Piaget proposed, but it also shows that young children are more capable, and their development more continuous, than he believed.

Lev Vygotsky's studies of child development focused on the ways a child's mind grows by interacting with the social environment. In his view, parents and caretakers provide temporary scaffolds enabling children to step to higher levels of learning.

5-6 What is autism spectrum disorder?

Autism spectrum disorder (ASD) is a disorder marked by social deficiencies and repetitive behaviors. By age 8, 1 in 68 U.S. children now gets diagnosed with ASD, though

the reported rates vary by place. The increase in ASD diagnoses has been offset by a decrease in the number of children with a “cognitive disability” or “learning disability,” suggesting a relabeling of children’s disorders.

5-7 How do parent-infant attachment bonds form?

At about 8 months, soon after object permanence develops, children separated from their caregivers display *stranger anxiety*. Infants form *attachments* not simply because parents gratify biological needs but, more important, because they are comfortable, familiar, and responsive. Many birds and other animals have a more rigid attachment process, called *imprinting*, that occurs during a *critical period*.

5-8 How have psychologists studied attachment differences, and what have they learned?

Attachment has been studied in strange situation experiments, which show that some children are securely attached and others are insecurely attached. Infants’ differing attachment styles reflect both their individual temperament and the responsiveness of their parents and child-care providers. Adult relationships seem to reflect the attachment styles of early childhood, lending support to Erik Erikson’s idea that *basic trust* is formed in infancy by our experiences with responsive caregivers.

5-9 How does childhood neglect or abuse affect children’s attachments?

Children are very resilient, but those who are severely neglected by their parents, or otherwise prevented from forming attachments at an early age, may be at risk for attachment problems.

5-10 How do children’s self-concepts develop?

Self-concept, an understanding and evaluation of who we are, emerges gradually. By 15 to 18 months, children recognize themselves in a mirror. By school age, they can describe many of their own traits, and by age 8 or 10 their self-image is stable.

5-11 What are three parenting styles, and how do children’s traits relate to them?

Parenting styles—authoritarian, permissive, and authoritative—reflect varying degrees of control. Children with high self-esteem tend to have authoritative parents and to be self-reliant and socially competent, but the direction of cause and effect in this relationship is not clear. Child-raising practices reflect both individual and cultural values.

Adolescence

5-12 How is *adolescence* defined, and how do physical changes affect developing teens?

Adolescence is the transition period from childhood to adulthood, extending from *puberty* to social independence. Boys seem to benefit (though with risks) from “early” maturation, girls from “late” maturation. The brain’s frontal lobes mature and myelin growth increases during adolescence and the early twenties, enabling improved judgment, impulse control, and long-term planning.

5-13 How did Piaget, Kohlberg, and later researchers describe adolescent cognitive and moral development?

Piaget theorized that adolescents develop a capacity for formal operations and that this development is the foundation for moral judgment. Lawrence Kohlberg proposed a stage theory of moral reasoning, from a preconventional morality of self-interest, to a conventional morality concerned with upholding laws and social rules, to (in some people) a postconventional morality of universal ethical principles. Other researchers believe that morality lies in moral intuition and moral action as well as thinking. Some

critics argue that Kohlberg's postconventional level represents morality from the perspective of individualist, middle-class people.

5-14 What are the social tasks and challenges of adolescence?

Erikson theorized that each life stage has its own psychosocial task, and that a chief task of adolescence is solidifying one's sense of self—one's *identity*. This often means trying out a number of different roles. *Social identity* is the part of the self-concept that comes from a person's group memberships.

5-15 How do parents and peers influence adolescents?

During adolescence, parental influence diminishes and peer influence increases, in part because of the selection effect—the tendency to choose similar others. But adolescents also do adopt their peers' ways of dressing, acting, and communicating. Parents have more influence in religion, politics, and college and career choices.

5-16 What is emerging adulthood?

The transition from adolescence to adulthood is now taking longer. *Emerging adulthood* is the period from age 18 to the mid-twenties, when many young people are not yet fully independent. But observers note that this stage is found mostly in today's Western cultures.

Adulthood

5-17 What physical changes occur during middle and late adulthood?

Muscular strength, reaction time, sensory abilities, and cardiac output begin to decline in the late twenties and continue to decline throughout middle adulthood (roughly age 40 to 65) and late adulthood (the years after 65). Women's period of fertility ends with *menopause* around age 50; men have no similar age-related sharp drop in hormone levels or fertility. In late adulthood, the immune system weakens, increasing susceptibility to life-threatening illnesses. Chromosome tips (telomeres) wear down, reducing the chances of normal genetic replication. But for some, longevity-supporting genes, low stress, and good health habits enable better health in later life.

5-18 How does memory change with age?

As the years pass, recall begins to decline, especially for meaningless information, but recognition memory remains strong. Older adults rely more on time management and memory cues to remember time-based and habitual tasks. Developmental researchers study age-related changes such as in memory with *cross-sectional studies* (comparing people of different ages) and *longitudinal studies* (retesting the same people over a period of years). "Terminal decline" describes the cognitive decline in the final few years of life.

5-19 How do neurocognitive disorders and Alzheimer's disease affect cognitive ability?

Neurocognitive disorders (NCDs) are acquired (not lifelong) disorders marked by cognitive deficits, which are often related to Alzheimer's disease, brain injury or disease, or substance abuse. This damage to brain cells results in the erosion of mental abilities that is not typical of normal aging. *Alzheimer's disease* is marked by neural plaques, often with an onset after age 80, entailing a progressive decline in memory and other cognitive abilities.

5-20 What themes and influences mark our social journey from early adulthood to death?

Adults do not progress through an orderly sequence of age-related social stages. Chance events can determine life choices. The *social clock* is a culture's preferred timing for

social events, such as marriage, parenthood, and retirement. Adulthood's dominant themes are love and work, which Erikson called intimacy and generativity.

5-21 How does our well-being change across the life span?

Self-confidence tends to strengthen across the life span. Surveys show that life satisfaction is unrelated to age. Positive emotions increase after midlife and negative ones decrease.

5-22 A loved one's death triggers what range of reactions?

People do not grieve in predictable stages, as was once supposed. Strong expressions of emotion do not purge grief, and bereavement therapy is not significantly more effective than grieving without such aid. Erikson viewed the late-adulthood psychosocial task as developing a sense of integrity (versus despair).

CHAPTER 6

SENSATION AND PERCEPTION

Basic Concepts of Sensation and Perception

6-1 What are *sensation* and *perception*? What do we mean by *bottom-up processing* and *top-down processing*?

Sensation is the process by which our sensory receptors and nervous system receive and represent stimulus energies from our environment. *Perception* is the process of organizing and interpreting this information, enabling recognition of meaningful events. Sensation and perception are actually parts of one continuous process. *Bottom-up processing* is sensory analysis that begins at the entry level, with information flowing from the sensory receptors to the brain. *Top-down processing* is information processing guided by high-level mental processes, as when we construct perceptions by filtering information through our experience and expectations.

6-2 What three steps are basic to all our sensory systems?

Our senses (1) receive sensory stimulation (often using specialized receptor cells); (2) transform that stimulation into neural impulses; and (3) deliver the neural information to the brain. *Transduction* is the process of converting one form of energy into another. Researchers in *psychophysics* study the relationships between stimuli's physical characteristics and our psychological experience of them.

6-3 How do *absolute thresholds* and *difference thresholds* differ, and what effect, if any, do stimuli below the absolute threshold have on us?

Our *absolute threshold* for any stimulus is the minimum stimulation necessary for us to be consciously aware of it 50 percent of the time. *Signal detection theory* predicts how and when we will detect a faint stimulus amid background noise. Individual absolute thresholds vary, depending on the strength of the signal and also on our experience, expectations, motivation, and alertness. Our *difference threshold* (also called *just noticeable difference*, or *jnd*) is the difference we can discern between two stimuli 50 percent of the time. *Weber's law* states that two stimuli must differ by a constant minimum percentage (not a constant amount) to be perceived as different.

Priming (the often unconscious activation of certain associations that may predispose one's perception, memory, or response) shows that we process some information from stimuli below our absolute threshold for conscious awareness.

6-4 Does subliminal sensation enable subliminal persuasion?

Subliminal stimuli are those that are too weak to detect 50 percent of the time. While subliminal sensation is a fact, such sensations are too fleeting to enable exploitation with subliminal messages: There is no powerful, enduring effect.

6-5 What is the function of sensory adaptation?

Sensory adaptation (our diminished sensitivity to constant or routine odors, sounds, and touches) focuses our attention on informative changes in our environment.

6-6 How do our expectations, contexts, motivation, and emotions influence our perceptions?

Perceptual set is a mental predisposition that functions as a lens through which we perceive the world. Our learned concepts (schemas) prime us to organize and interpret ambiguous stimuli in certain ways. Our physical and emotional context, as well as our motivation, can create expectations and color our interpretation of events and behaviors.

Vision: Sensory and Perceptual Processing

6-7 What are the characteristics of the energy that we see as visible light? What structures in the eye help focus that energy?

What we see as light is only a thin slice of the broad spectrum of electromagnetic energy. The portion visible to humans extends from the blue-violet to the red light wavelengths. After entering the eye and being focused by a *lens*, light energy particles strike the eye's inner surface, the *retina*. The *hue* we perceive in a light depends on its *wavelength*, and its brightness depends on its *intensity*.

6-8 How do the rods and cones process information, and what is the path information travels from the eye to the brain?

Light entering the eye triggers chemical reaction in the light-sensitive *rods* and color-sensitive *cones* at the back of the retina, which converts light energy into neural impulses. After processing by bipolar and ganglion cells, neural impulses travel from the retina through the *optic nerve* to the thalamus, and on to the visual cortex.

6-9 How do we perceive color in the world around us?

According to the *Young-Helmholtz trichromatic (three-color) theory*, the retina contains three types of color receptors. Contemporary research has found three types of cones, each most sensitive to the wavelengths of one of the three primary colors of light (red, green, or blue).

Hering's *opponent-process theory* proposed three additional color processes (red-versus-green, blue-versus-yellow, black-versus-white). Research has confirmed that, en route to the brain, neurons in the retina and the thalamus code the color-related information from the cones into pairs of opponent colors.

These two theories, and the research supporting them, show that color processing occurs in two stages.

6-10 Where are feature detectors located, and what do they do?

Feature detectors, located in the visual cortex, respond to specific features of the visual stimulus, such as shape, angle, or movement. Supercell clusters in other critical areas respond to more complex patterns.

6-11 How does the brain use parallel processing to construct visual perceptions?

Through *parallel processing*, the brain handles many aspects of vision (color, movement, form, and depth) simultaneously. Other neural teams integrate the results, comparing them with stored information and enabling perceptions.

6-12 How did the Gestalt psychologists understand perceptual organization, and how do figure-ground and grouping principles contribute to our perceptions?

Gestalt psychologists searched for rules by which the brain organizes fragments of sensory data into *gestalts* (from the German word for "whole"), or meaningful forms. In

pointing out that the whole may exceed the sum of its parts, they noted that we filter sensory information and construct our perceptions.

To recognize an object, we must first perceive it (see it as a *figure*) as distinct from its surroundings (the *ground*). We bring order and form to stimuli by organizing them into meaningful *groups*, following such rules as proximity, continuity, and closure.

6-13 How do we use binocular and monocular cues to perceive the world in three dimensions, and how do we perceive motion?

Depth perception is our ability to see objects in three dimensions and judge distance. The *visual cliff* and other research demonstrate that many species perceive the world in three dimensions at, or very soon after, birth. *Binocular cues*, such as *retinal disparity*, are depth cues that rely on information from both eyes. *Monocular cues* (such as relative size, interposition, relative height, relative motion, linear perspective, and light and shadow) let us judge depth using information transmitted by only one eye.

As objects move, we assume that shrinking objects are retreating and enlarging objects are approaching. A quick succession of images on the retina can create an illusion of movement, as in stroboscopic movement or the *phi phenomenon*.

6-14 How do perceptual constancies help us construct meaningful perceptions?

Perceptual constancy enables us to perceive objects as stable despite the changing image they cast on our retinas. *Color constancy* is our ability to perceive consistent color in objects, even though the lighting and wavelengths shift. Brightness (or lightness) constancy is our ability to perceive an object as having a constant lightness even when its illumination—the light cast upon it—changes. Our brain constructs our experience of an object's color or brightness through comparisons with other surrounding objects.

Shape constancy is our ability to perceive familiar objects (such as an opening door) as unchanging in shape. Size constancy is perceiving objects as unchanging in size despite their changing retinal images. Knowing an object's size gives us clues to its distance; knowing its distance gives clues about its size, but we sometimes misread monocular distance cues and reach the wrong conclusions, as in the Moon illusion.

6-15 What does research on restored vision, sensory restriction, and perceptual adaptation reveal about the effects of experience on perception?

Experience guides our perceptual interpretations. People blind from birth who gained sight after surgery lack the experience to visually recognize shapes, forms, and complete faces.

Sensory restriction research indicates that there is a critical period for some aspects of sensory and perceptual development. Without early stimulation, the brain's neural organization does not develop normally.

People given glasses that shift the world slightly to the left or right, or even upside down, experience *perceptual adaptation*. They are initially disoriented, but they manage to adapt to their new context.

The Nonvisual Senses

6-16 What are the characteristics of air pressure waves that we hear as sound?

Sound waves are bands of compressed and expanded air. Our ears detect these changes in air pressure and transform them into neural impulses, which the brain decodes as sound. Sound waves vary in amplitude, which we perceive as differing loudness, and in *frequency*, which we experience as differing *pitch*.

6-17 How does the ear transform sound energy into neural messages?

The outer ear is the visible portion of the ear. The *middle ear* is the chamber between the eardrum and *cochlea*. The *inner ear* consists of the cochlea, semicircular canals,

and vestibular sacs. Through a mechanical chain of events, sound waves traveling through the auditory canal cause tiny vibrations in the eardrum. The bones of the middle ear amplify the vibrations and relay them to the fluid-filled cochlea. Rippling of the basilar membrane, caused by pressure changes in the cochlear fluid, causes movement of the tiny hair cells, triggering neural messages to be sent (via the thalamus) to the auditory cortex in the brain.

Sensorineural hearing loss (or nerve deafness) results from damage to the cochlea's hair cells or their associated nerves. *Conduction hearing loss* results from damage to the mechanical system that transmits sound waves to the cochlea. *Cochlear implants* can restore hearing for some people.

6-18 How do we detect loudness, discriminate pitch, and locate sounds?

Loudness is not related to the intensity of a hair cell's response. The brain interprets loudness from the number of activated hair cells.

Place theory explains how we hear high-pitched sounds, and *frequency theory* explains how we hear low-pitched sounds. (A combination of the two theories explains how we hear pitches in the middle range.) Place theory proposes that our brain interprets a particular pitch by decoding the place where a sound wave stimulates the cochlea's basilar membrane. *Frequency theory* proposes that the brain deciphers the frequency of the neural impulses traveling up the auditory nerve to the brain.

Sound waves strike one ear sooner and more intensely than the other. To locate sounds, the brain analyzes the minute differences in the sounds received by the two ears and computes the sound's source.

6-19 How do we sense touch?

Our sense of touch is actually several senses—pressure, warmth, cold, and pain—that combine to produce other sensations, such as “hot.”

6-20 What biological, psychological, and social-cultural influences affect our experience of pain? How do placebos, distraction, and hypnosis help control pain?

Pain reflects bottom-up sensations (such as input from *nociceptors*, the sensory receptors that detect hurtful temperatures, pressure, or chemicals) and top-down processes (such as experience, attention, and culture). One theory of pain is that a “*gate*” in the spinal cord either opens to permit pain signals traveling up small nerve fibers to reach the brain, or closes to prevent their passage. The biopsychosocial perspective views our perception of pain as the sum of biological, psychological, and social-cultural influences. For example, our experience of pain is influenced by activity in the spinal cord's large and small fibers (a biological influence), attention to pain (a psychological influence), and cultural expectations (a social-cultural influence).

Pain treatments often combine physical and psychological elements. Placebos can help by dampening the central nervous system's attention and response to painful experiences. Distractions draw people's attention away from painful stimulation. *Hypnosis*, which increases our response to suggestions, can also help relieve pain. *Posthypnotic suggestion* is used by some clinicians to control undesired symptoms.

6-21 In what ways are our senses of taste and smell similar, and how do they differ?

Taste and smell are both chemical senses. Taste is a composite of five basic sensations—sweet, sour, salty, bitter, and umami—and of the aromas that interact with information from the taste receptor cells of the taste buds.

There are no basic sensations for smell. We smell something when molecules of a substance carried in the air reach a tiny cluster of 20 million receptor cells at the top of each nasal cavity. Odor molecules trigger combinations of receptors, in patterns that

the olfactory cortex interprets. The receptor cells send messages to the brain's olfactory bulb, then to the temporal lobe, and to parts of the limbic system.

6-22 How do we sense our body's position and movement?

Through *kinesthesia*, we sense the position and movement of our body parts. We monitor our head's (and thus our body's) position and movement, and maintain our balance, with our *vestibular sense*.

6-23 How does *sensory interaction* influence our perceptions, and what is *embodied cognition*?

Our senses can influence one another. This *sensory interaction* occurs, for example, when the smell of a favorite food amplifies its taste. *Embodied cognition* is the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments.

6-24 What are the claims of ESP, and what have most research psychologists concluded after putting these claims to the test?

Parapsychology is the study of paranormal phenomena, including *extrasensory perception* (ESP) and psychokinesis. The three most testable forms of ESP are telepathy (mind-to-mind communication), clairvoyance (perceiving remote events), and precognition (perceiving future events).

Skeptics argue that (1) to believe in ESP, you must believe the brain is capable of perceiving without sensory input, and (2) researchers have been unable to replicate ESP phenomena under controlled conditions.

CHAPTER 7

LEARNING

Basic Learning Concepts and Classical Conditioning

7-1 What is *learning*, and what are some basic forms of learning?

Learning is the process of acquiring through experience new information or behaviors. In *associative learning*, we learn that certain events occur together. In classical conditioning, we learn to associate two or more stimuli (a *stimulus* is any event or situation that evokes a response). We associate stimuli that we do not control, and we respond automatically. This is called *respondent behavior*. In operant conditioning, we learn to associate a response and its consequences. These associations produce *operant behaviors*. Through *cognitive learning*, we acquire mental information that guides our behavior. For example, in observational learning, we learn new behaviors by observing events and watching others.

7-2 What was behaviorism's view of learning?

Ivan Pavlov's work on classical conditioning laid the foundation for *behaviorism*, the view that psychology should be an objective science that studies behavior without reference to mental processes. The behaviorists believed that the basic laws of learning are the same for all species, including humans.

7-3 Who was Pavlov, and what are the basic components of classical conditioning?

Ivan Pavlov, a Russian physiologist, created novel experiments on learning. His early twentieth-century research over the last three decades of his life demonstrated that classical conditioning is a basic form of learning.

Classical conditioning is a type of learning in which an organism comes to associate stimuli. In classical conditioning, an NS is a stimulus that elicits no response before conditioning. A UR is an event that occurs naturally (such as salivation), in response to

some stimulus. A *US* is something that naturally and automatically (without learning) triggers the unlearned response (as food in the mouth triggers salivation). A *CS* is a previously neutral stimulus (such as a tone) that, after association with a *US* (such as food) comes to trigger a *CR*. A *CR* is the learned response (salivating) to the originally neutral (but now conditioned) stimulus.

7-4 In classical conditioning, what are the processes of acquisition, extinction, spontaneous recovery, generalization, and discrimination?

In classical conditioning, *acquisition* is associating an *NS* with the *US* so that the *NS* begins triggering the *CR*. Acquisition occurs most readily when the *NS* is presented just before (ideally, about a half-second before) a *US*, preparing the organism for the upcoming event. This finding supports the view that classical conditioning is biologically adaptive. Through higher-order conditioning, a new *NS* can become a new *CS*.

Extinction is diminished responding when the *CS* no longer signals an impending *US*. *Spontaneous recovery* is the appearance of a formerly extinguished response, following a rest period. *Generalization* is the tendency to respond to stimuli that are similar to a *CS*. *Discrimination* is the learned ability to distinguish between a *CS* and other irrelevant stimuli.

7-5 Why does Pavlov's work remain so important?

Pavlov taught us that significant psychological phenomena can be studied objectively, and that classical conditioning is a basic form of learning that applies to all species.

7-6 What have been some applications of Pavlov's work to human health and well-being? How did Watson apply Pavlov's principles to learned fears?

Classical conditioning techniques are used to improve human health and well-being in many areas, including behavioral therapy for some types of psychological disorders. The body's immune system may also respond to classical conditioning.

Pavlov's work also provided a basis for Watson's idea that human emotions and behaviors, though biologically influenced, are mainly a bundle of conditioned responses. Watson applied classical conditioning principles in his studies of "Little Albert" to demonstrate how specific fears might be conditioned.

Operant Conditioning

7-7 What is operant conditioning?

In *operant conditioning*, behaviors followed by reinforcers increase; those followed by punishers often decrease.

7-8 Who was Skinner, and how is operant behavior reinforced and shaped?

B. F. Skinner was a college English major and aspiring writer who later entered psychology graduate school. He became modern behaviorism's most influential and controversial figure.

Expanding on Edward Thorndike's *law of effect*, Skinner and others found that the behavior of rats or pigeons placed in an *operant chamber* (Skinner box) can be *shaped* by using reinforcers to guide closer and closer approximations of the desired behavior.

7-9 How do positive and negative reinforcement differ, and what are the basic types of reinforcers?

Reinforcement is any consequence that strengthens behavior. *Positive reinforcement* adds a desirable stimulus to increase the frequency of a behavior. *Negative reinforcement* removes an aversive stimulus to increase the frequency of a behavior.

Primary reinforcers (such as receiving food when hungry or having nausea end during an illness) are innately satisfying—no learning is required. *Conditioned* (or secondary)

reinforcers (such as cash) are satisfying because we have learned to associate them with more basic rewards (such as the food or medicine we buy with them). Immediate reinforcers (such as a purchased treat) offer immediate payback; delayed reinforcers (such as a weekly paycheck) require the ability to delay gratification.

7-10 How do different reinforcement schedules affect behavior?

A *reinforcement schedule* defines how often a response will be reinforced. In *continuous reinforcement* (reinforcing desired responses every time they occur), learning is rapid, but so is extinction if rewards cease. In *partial (intermittent) reinforcement* (reinforcing responses only sometimes), initial learning is slower, but the behavior is much more resistant to extinction. *Fixed-ratio schedules* reinforce behaviors after a set number of responses; *variable-ratio schedules*, after an unpredictable number. *Fixed-interval schedules* reinforce behaviors after set time periods; *variable-interval schedules*, after unpredictable time periods.

7-11 How does punishment differ from negative reinforcement, and how does punishment affect behavior?

Punishment administers an undesirable consequence (such as spanking) or withdraws something desirable (such as taking away a favorite toy) in an attempt to decrease the frequency of a behavior (a child's disobedience). Negative reinforcement (taking an aspirin) removes an aversive stimulus (a headache). This desired consequence (freedom from pain) increases the likelihood that the behavior (taking aspirin to end pain) will be repeated.

Punishment can have undesirable side effects, such as suppressing rather than changing unwanted behaviors; teaching aggression; creating fear; encouraging discrimination (so that the undesirable behavior appears when the punisher is not present); and fostering depression and feelings of helplessness.

7-12 Why did Skinner's ideas provoke controversy, and how might his operant conditioning principles be applied at school, in sports, at work, and at home?

Critics of Skinner's principles believed the approach dehumanized people by neglecting their personal freedom and seeking to control their actions. Skinner replied that people's actions are already controlled by external consequences, and that reinforcement is more humane than punishment as a means for controlling behavior.

At school, teachers can use shaping techniques to guide students' behaviors, and they can use interactive software and websites to provide immediate feedback. In sports, coaches can build players' skills and self-confidence by rewarding small improvements. At work, managers can boost productivity and morale by rewarding well-defined and achievable behaviors. At home, parents can reward desired behaviors but not undesirable ones. We can shape our own behaviors by stating our goals, monitoring the frequency of desired behaviors, reinforcing desired behaviors, and gradually reducing rewards as behaviors become habitual.

7-13 How does operant conditioning differ from classical conditioning?

In operant conditioning, an organism learns associations between its own behavior and resulting events; this form of conditioning involves operant behavior (behavior that operates on the environment, producing rewarding or punishing consequences). In classical conditioning, the organism forms associations between stimuli—events it does not control; this form of conditioning involves respondent behavior (automatic responses to some stimulus).

Biology, Cognition, and Learning

7-14 How do biological constraints affect classical and operant conditioning?

Classical conditioning principles, we now know, are constrained by biological predispositions, so that learning some associations is easier than learning others. Learning is

adaptive: Each species learns behaviors that aid its survival. Biological constraints also place limits on operant conditioning. Training that attempts to override biological constraints will probably not endure because animals will revert to predisposed patterns.

7-15 How do cognitive processes affect classical and operant conditioning?

In classical conditioning, animals may learn when to expect a US and may be aware of the link between stimuli and responses. In operant conditioning, *cognitive mapping* and *latent learning* research demonstrate the importance of cognitive processes in learning. Other research shows that excessive rewards (driving *extrinsic motivation*) can undermine *intrinsic motivation*.

7-16 How does observational learning differ from associative learning? How may observational learning be enabled by mirror neurons?

In *observational learning*, as we observe and imitate others we learn to anticipate a behavior's consequences because we experience vicarious reinforcement or vicarious punishment. In associative learning, we merely learn associations between different events.

Our brain's frontal lobes have a demonstrated ability to mirror the activity of another's brain. Some psychologists believe *mirror neurons* enable this process. The same areas fire when we perform certain actions (such as responding to pain or moving our mouth to form words) as when we observe someone else performing those actions.

7-17 What is the impact of prosocial modeling and of antisocial modeling?

Children tend to imitate what a model does and says, whether the behavior being *modeled* is *prosocial* (positive, constructive, and helpful) or antisocial. If a model's actions and words are inconsistent, children may imitate the hypocrisy they observe.

CHAPTER 8

MEMORY

Studying and Encoding Memories

8-1 What is memory, and how is it measured?

Memory is learning that has persisted over time, through the encoding, storage, and retrieval of information. Evidence of memory may be *recalling* information, *recognizing* it, or *relearning* it more easily on a later attempt.

8-2 How do psychologists describe the human memory system?

Psychologists use memory models to think and communicate about memory. Information-processing models involve three processes: *encoding*, *storage*, and *retrieval*. Our agile brain processes many things simultaneously (some of them unconsciously) by means of *parallel processing*. The connectionism information-processing model focuses on this multitrack processing, viewing memories as products of interconnected neural networks. The three processing stages in the Atkinson-Shiffrin model are *sensory memory*, *short-term memory*, and *long-term memory*. This model has since been updated to include two important concepts: (1) *working memory*, to stress the active processing occurring in the second memory stage; and (2) automatic processing, to address the processing of information outside of conscious awareness.

8-3 How do explicit and implicit memories differ?

The human brain processes information on dual tracks, consciously and unconsciously. *Explicit* (declarative) *memories*—our conscious memories of facts and experiences—form through *effortful processing*, which requires conscious effort and attention. *Implicit* (nondeclarative) *memories*—of skills and classically conditioned associations—happen without our awareness, through *automatic processing*.

8-4 What information do we process automatically?

In addition to skills and classically conditioned associations, we automatically process incidental information about space, time, and frequency.

8-5 How does sensory memory work?

Sensory memory feeds some information into working memory for active processing there. An *iconic memory* is a very brief (a few tenths of a second) sensory memory of visual stimuli; an *echoic memory* is a three- or four-second sensory memory of auditory stimuli.

8-6 What is the capacity of our short-term and working memory?

Short-term memory capacity is about seven items, plus or minus two, but this information disappears from memory quickly without rehearsal. Working memory capacity varies, depending on age, intelligence level, and other factors.

8-7 What are some effortful processing strategies that can help us remember new information?

Effective effortful processing strategies include *chunking*, *mnemonics*, hierarchies, and distributed practice sessions. The *testing effect* is enhanced memory after consciously retrieving, rather than simply rereading, information.

8-8 What are the levels of processing, and how do they affect encoding?

Depth of processing affects long-term retention. In *shallow processing*, we encode words based on their structure or appearance. Retention is best when we use *deep processing*, encoding words based on their meaning. We also more easily remember material that is personally meaningful—the self-reference effect.

Storing and Retrieving Memories

8-9 What is the capacity of long-term memory? Are our long-term memories processed and stored in specific locations?

Our long-term memory capacity is essentially unlimited. Memories are not stored intact in the brain in single spots. Many parts of the brain interact as we encode, store, and retrieve memories.

8-10 What are the roles of the frontal lobes and hippocampus in memory processing?

The frontal lobes and *hippocampus* are parts of the brain network dedicated to explicit memory formation. Many brain regions send information to the frontal lobes for processing. The hippocampus, with the help of surrounding areas of cortex, registers and temporarily holds elements of explicit memories before moving them to other brain regions for long-term storage. The neural storage of long-term memories is called *memory consolidation*.

8-11 What roles do the cerebellum and basal ganglia play in memory processing?

The cerebellum and basal ganglia are parts of the brain network dedicated to implicit memory formation. The cerebellum is important for storing classically conditioned memories. The basal ganglia are involved in motor movement and help form procedural memories for skills. Many reactions and skills learned during our first three years continue into our adult lives, but we cannot consciously remember learning these associations and skills, a phenomenon psychologists call “infantile amnesia.”

8-12 How do emotions affect our memory processing?

Emotional arousal causes an outpouring of stress hormones, which lead to activity in the brain’s memory-forming areas. Significantly stressful events can trigger very clear *flashbulb memories*.

8-13 How do changes at the synapse level affect our memory processing?

Long-term potentiation (LTP) appears to be the neural basis of learning. In LTP, neurons become more efficient at releasing and sensing the presence of neurotransmitters, and more connections develop between neurons.

8-14 How do external cues, internal emotions, and order of appearance influence memory retrieval?

External cues activate associations that help us retrieve memories; this process may occur without our awareness, as it does in *priming*. The *encoding specificity principle* is the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it. Returning to the same physical context or emotional state (*mood congruency*) in which we formed a memory can help us retrieve it. The *serial position effect* accounts for our tendency to recall best the last items (which may still be in working memory) and the first items (which we've spent more time rehearsing) in a list.

Forgetting, Memory Construction, and Improving Memory

8-15 Why do we forget?

Anterograde amnesia is an inability to form new memories. *Retrograde amnesia* is an inability to retrieve old memories. Normal forgetting can happen because we have never encoded information (encoding failure); because the physical trace has decayed (storage decay); or because we cannot retrieve what we have encoded and stored (retrieval failure). Retrieval problems may result from *proactive* (forward-acting) *interference*, as prior learning interferes with recall of new information, or from *retroactive* (backward-acting) *interference*, as new learning disrupts recall of old information. Some believe that motivated forgetting occurs, but researchers have found little evidence of *repression*.

8-16 How do misinformation, imagination, and source amnesia influence our memory construction? How do we decide whether a memory is real or false?

In experiments demonstrating the *misinformation effect*, people have formed false memories, incorporating misleading details, after receiving wrong information after an event, or after repeatedly imagining and rehearsing something that never happened. When we reassemble a memory during retrieval, we may attribute it to the wrong source (*source amnesia*). Source amnesia may help explain *déjà vu*. False memories feel like real memories and can be persistent but are usually limited to the gist of the event.

8-17 How reliable are young children's eyewitness descriptions?

Children are susceptible to the misinformation effect, but if questioned in neutral words they understand, they can accurately recall events and people involved in them.

8-18 Why are reports of repressed and recovered memories so hotly debated?

The debate (between memory researchers and some well-meaning therapists) focuses on whether most memories of early childhood abuse are repressed and can be recovered during therapy using "memory work" techniques using leading questions or hypnosis. Psychologists now agree that (1) sexual abuse happens; (2) injustice happens; (3) forgetting happens; (4) recovered memories are commonplace; (5) memories of things that happened before age 3 are unreliable; (6) memories "recovered" under hypnosis or the influence of drugs are especially unreliable; and (7) memories, whether real or false, can be emotionally upsetting.

8-19 How can you use memory research findings to do better in this and other courses?

Memory research findings suggest the following strategies for improving memory: Study repeatedly, make material meaningful, activate retrieval cues, use mnemonic devices, minimize interference, sleep more, and test yourself to be sure you can retrieve, as well as recognize, material.

CHAPTER 9

THINKING AND LANGUAGE

Thinking

9-1 What is cognition, and what are the functions of concepts?

Cognition refers to all the mental activities associated with thinking, knowing, remembering, and communicating. We use *concepts*, mental groupings of similar objects, events, ideas, or people, to simplify and order the world around us. We form most concepts around *prototypes*, or best examples of a category.

9-2 What cognitive strategies assist our problem solving, and what obstacles hinder it?

An *algorithm* is a methodical, logical rule or procedure (such as a step-by-step description for evacuating a building during a fire) that guarantees a solution to a problem. A *heuristic* is a simpler strategy (such as running for an exit if you smell smoke) that is usually speedier than an algorithm but is also more error prone. *Insight* is not a strategy-based solution, but rather a sudden flash of inspiration that solves a problem.

Obstacles to problem solving include *confirmation bias*, which predisposes us to verify rather than challenge our hypotheses, and fixation, such as *mental set*, which may prevent us from taking the fresh perspective that would lead to a solution.

9-3 What is intuition, and how can the availability heuristic, overconfidence, belief perseverance, and framing influence our decisions and judgments?

Intuition is the effortless, immediate, automatic feelings or thoughts we often use instead of systematic reasoning. Heuristics enable snap judgments. Using the *availability heuristic*, we judge the likelihood of things based on how readily they come to mind, which often leads us to fear the wrong things. *Overconfidence* can lead us to overestimate the accuracy of our beliefs. When a belief we have formed and explained has been discredited, *belief perseverance* may cause us to cling to that belief. A remedy for belief perseverance is to consider how we might have explained an opposite result. *Framing* is the way a question or statement is worded. Subtle wording differences can dramatically alter our responses.

9-4 What factors contribute to our fear of unlikely events?

We tend to be afraid of what our ancestral history has prepared us to fear (thus, snakes instead of cigarettes); what we cannot control (flying instead of driving); what is immediate (the takeoff and landing of flying instead of countless moments of trivial danger while driving); and what is most readily available (vivid images of air disasters instead of countless safe car trips).

9-5 How do smart thinkers use intuition?

As people gain expertise, they grow adept at making quick, shrewd judgments. Smart thinkers welcome their intuitions (which are usually adaptive), but when making complex decisions they gather as much information as possible and then take time to let their two-track mind process all available information.

9-6 What is creativity, and what fosters it?

Creativity, the ability to produce novel and valuable ideas, correlates somewhat with aptitude, but is more than school smarts. Aptitude tests require *convergent thinking*, but creativity requires *divergent thinking*. Robert Sternberg has proposed that creativity has five components: expertise; imaginative thinking skills; a venturesome personality; intrinsic motivation; and a creative environment that sparks, supports, and refines creative ideas.

9-7 What do we know about thinking in other animals?

Researchers make inferences about other species' consciousness and intelligence based on behavior. Evidence from studies of various species shows that other animals use concepts, numbers, and tools and that they transmit learning from one generation to the next (cultural transmission). And, like humans, other species also show insight, self-awareness, altruism, cooperation, and grief.

Language and Thought

9-8 What are the structural components of a language?

Phonemes are a language's basic units of sound. *Morphemes* are the elementary units of meaning. *Grammar*—the system of rules that enables us to communicate—includes semantics (rules for deriving meaning) and syntax (rules for ordering words into sentences).

9-9 What are the milestones in language development, and how do we acquire language?

Language development's timing varies, but all children follow the same sequence. Receptive language (the ability to understand what is said to or about you) develops before productive language (the ability to produce words). At about 4 months of age, infants *babble*, making sounds found in languages from all over the world. By about 10 months, their babbling contains only the sounds found in their household language. Around 12 months of age, children begin to speak in single words. This *one-word stage* evolves into *two-word (telegraphic)* utterances before their second birthday, after which they begin speaking in full sentences.

Linguist Noam Chomsky has proposed that all human languages share a universal grammar—the basic building blocks of language—and that humans are born with a predisposition to learn language. We acquire a specific language through learning as our biology and experience interact. Childhood is a critical period for learning to speak and/or sign fluently. This is an important consideration for parents of deaf children, who might master oral communication if given a cochlear implant during this critical period. Deaf culture advocates oppose such implants on the grounds that deafness is a difference, not a disability.

9-10 What brain areas are involved in language processing and speech?

Aphasia is an impairment of language, usually caused by left-hemisphere damage. Two important language- and speech-processing areas are *Broca's area*, a region of the frontal lobe that controls language expression, and *Wernicke's area*, a region in the left temporal lobe that controls language reception. Language processing is spread across other brain areas as well, where different neural networks handle specific linguistic subtasks.

9-11 What do we know about other animals' capacity for language?

A number of chimpanzees and bonobos have (1) learned to communicate with humans by signing or by pushing buttons wired to a computer, (2) developed vocabularies of nearly 400 words, (3) communicated by stringing these words together, (4) taught their skills to younger animals, and (5) demonstrated some understanding of syntax. But only humans communicate in complex sentences. Nevertheless, other animals' impressive abilities to think and communicate challenge humans to consider what this means about the moral rights of other species.

9-12 What is the relationship between thinking and language, and what is the value of thinking in images?

Although Benjamin Lee Whorf's *linguistic determinism* hypothesis suggested that language determines thought, it is in fact more accurate to say that language influences

thought. Different languages embody different ways of thinking, and immersion in bilingual education can enhance thinking. We often think in images when we use implicit (nondeclarative, procedural) memory—our automatic memory system for motor and cognitive skills and classically conditioned associations. Thinking in images can increase our skills when we mentally practice upcoming events.

CHAPTER 10

INTELLIGENCE

What Is Intelligence?

10-1 How do psychologists define *intelligence*, and what are the arguments for *g*?

Intelligence is a mental quality consisting of the potential to learn from experience, solve problems, and use knowledge to adapt to new situations. Charles Spearman proposed that we have one *general intelligence* (*g*) underlying all other specific mental abilities. He helped develop factor analysis, a statistical procedure that identifies clusters of related abilities. L. L. Thurstone disagreed and identified seven different clusters of mental abilities. Yet a tendency remained for high scorers in one cluster to score high in other clusters. Studies indicate that *g* scores are most predictive in novel situations and do not much correlate with skills in evolutionarily familiar situations.

10-2 How do Gardner's and Sternberg's theories of multiple intelligences differ, and what criticisms have they faced?

Savant syndrome seems to support Howard Gardner's view that we have multiple intelligences. He proposed eight independent intelligences: linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist. (He has also proposed a ninth possible intelligence—existential intelligence—the ability to ponder deep questions about life.) Robert Sternberg's triarchic theory proposes three intelligence areas that predict real-world skills: analytical (academic problem-solving), creative, and practical.

Critics note research that has confirmed a general intelligence factor. But highly successful people also tend to be conscientious, well-connected, and doggedly energetic.

10-3 What are the four components of emotional intelligence?

Emotional intelligence, which is an aspect of social intelligence, is the ability to perceive, understand, manage, and use emotions. Emotionally intelligent people achieve greater personal and professional success. Some critics question whether calling these abilities "intelligence" stretches that concept too far.

Assessing Intelligence

10-4 What is an intelligence test, and what is the difference between achievement and aptitude tests?

An *intelligence test* is a method for assessing an individual's mental aptitudes and comparing them with others, using numerical scores. *Aptitude tests* measure the ability to learn, while *achievement tests* measure what we have already learned.

10-5 When and why were intelligence tests created, and how do today's tests differ from early intelligence tests?

In the late 1800s, Francis Galton, who believed that genius was inherited, attempted but failed to construct a simple intelligence test. Alfred Binet, who tended toward an environmental explanation of intelligence differences, started the modern intelligence-testing movement in France in 1904 when he developed questions to help predict children's future progress in the Paris school system. During the early twentieth century,

Lewis Terman of Stanford University revised Binet's work for use in the United States. Terman believed intelligence was inherited, and he thought his *Stanford-Binet* could help guide people toward appropriate opportunities. From such tests, William Stern contributed the concept of the *IQ* (intelligence quotient). During this period, intelligence tests were sometimes used to “document” scientists' assumptions about the innate inferiority of certain ethnic and immigrant groups.

The most widely used intelligence tests today are the *Wechsler Adult Intelligence Scale* (WAIS) and Wechsler's tests for children. These tests differ from their predecessors in the way they offer an overall intelligence score as well as scores for various verbal and performance areas.

10-6 What is a normal curve, and what does it mean to say that a test has been standardized and is reliable and valid?

The distribution of test scores often forms a *normal* (bell-shaped) *curve* around the central average score, with fewer and fewer scores at the extremes.

Standardization establishes a basis for meaningful score comparisons by giving a test to a representative sample of future test-takers. *Reliability* is the extent to which a test yields consistent results (on two halves of the test, on alternative forms of the test, or when people are retested). *Validity* is the extent to which a test measures or predicts what it is supposed to. A test has *content validity* if it samples the pertinent behavior (as a driving test measures driving ability). It has *predictive validity* if it predicts a behavior it was designed to predict. (Aptitude tests have predictive ability if they can predict future achievements; their predictive power is best for the early school years.)

The Dynamics of Intelligence

10-7 How stable are intelligence test scores over the life span, and how does aging affect crystallized and fluid intelligence?

Cross-sectional studies (comparing people of different ages) and longitudinal studies (retesting the same group over a period of years) have shown that *fluid intelligence* declines in older adults, in part because neural processing slows. However, *crystallized intelligence* tends to increase.

The stability of intelligence test scores increases with age. At age 4, scores fluctuate somewhat but begin to predict adolescent and adult scores. By early adolescence, scores are very stable and predictive.

10-8 What are the traits of those at the low and high intelligence extremes?

At the low extreme are those with unusually low scores. An intelligence test score of or below 70 is one diagnostic criterion for the diagnosis of *intellectual disability*; other criteria are limited conceptual, social, and practical skills. One condition included in this category is *Down syndrome*, a developmental disorder caused by an extra copy of chromosome 21.

People at the high-intelligence extreme tend to be healthy and well-adjusted, as well as unusually successful academically. Schools sometimes “track” such children, separating them from students with lower scores. Such programs can become self-fulfilling prophecies as both groups live up to—or down to—others' perceptions and expectations.

Genetic and Environmental Influences on Intelligence

10-9 What evidence points to a genetic influence on intelligence, and what is heritability?

Studies of twins, family members, and adoptees indicate a significant hereditary contribution to intelligence scores. Intelligence seems to be polygenetic, and researchers are

searching for genes that exert an influence. *Heritability* is the proportion of variation among individuals that can be attributed to genes.

10-10 What does evidence reveal about environmental influences on intelligence?

Studies of twins, family members, and adoptees also provide evidence of environmental influences. Test scores of identical twins raised apart are slightly less similar (though still very highly correlated) than the scores of identical twins raised together. Studies of children raised in extremely impoverished environments with minimal social interaction indicate that life experiences can significantly influence intelligence test performance. No evidence supports the idea that normal, healthy children can be molded into geniuses by growing up in an exceptionally enriched environment.

10-11 How and why do the genders differ in mental ability scores?

Males and females tend to have the same average intelligence test scores, but they differ in some specific abilities. Girls are better spellers, more verbally fluent, better at locating objects, better at detecting emotions, and more sensitive to touch, taste, and color. Boys outperform girls at spatial ability and related mathematics, though in math computation and overall math performance, boys and girls hardly differ. Boys also outnumber girls at the low and high extremes of mental abilities. Evolutionary and cultural explanations have been proposed for these gender differences.

10-12 How and why do racial and ethnic groups differ in mental ability scores?

Racial and ethnic groups differ in their average intelligence test scores. The evidence suggests that environmental differences are responsible for these group differences.

10-13 Are intelligence tests inappropriately biased?

Aptitude tests aim to predict how well a test-taker will perform in a given situation. So they are necessarily “biased” in the sense that they are sensitive to performance differences caused by cultural experience. By “inappropriately biased,” psychologists mean that a test predicts less accurately for one group than for another. In this sense, most experts consider the major aptitude tests unbiased. *Stereotype threat*, a self-confirming concern that one will be evaluated based on a negative stereotype, affects performance on all kinds of tests.

CHAPTER 11

WHAT DRIVES US: HUNGER, SEX, FRIENDSHIP, AND ACHIEVEMENT

Basic Motivational Concepts

11-1 How do psychologists define *motivation*? From what perspectives do they view motivated behavior?

Motivation is a need or desire that energizes and directs behavior. The *instinct/evolutionary* perspective explores genetic influences on complex behaviors. *Drive-reduction theory* explores how physiological needs create aroused tension states (drives) that direct us to satisfy those needs. Environmental *incentives* can intensify drives. Drive-reduction’s goal is *homeostasis*, maintaining a steady internal state. Arousal theory proposes that some behaviors (such as those driven by curiosity) do not reduce physiological needs but rather are prompted by a search for an optimum level of arousal. The *Yerkes-Dodson law* states that performance increases with arousal, but only to a certain point, after which it decreases. Performance peaks at lower levels of arousal for difficult tasks, and at higher levels for easy or well-learned tasks. Abraham Maslow’s *hierarchy of needs* proposes a pyramid of human needs, from basic needs such as hunger and thirst up to higher-level needs such as self-actualization and self-transcendence.

Hunger

11-2 What physiological factors produce hunger?

Hunger pangs correspond to stomach contractions, but hunger also has other causes. Neural areas in the brain, some within the hypothalamus, monitor blood chemistry (including level of *glucose*) and incoming information about the body's state. Appetite hormones include ghrelin (secreted by an empty stomach); insulin (controls blood glucose); leptin (secreted by fat cells); orexin (secreted by the hypothalamus); and PYY (secreted by the digestive tract). *Basal metabolic rate* is the body's resting rate of energy expenditure. The body may have a *set point* (a biologically fixed tendency to maintain an optimum weight) or a looser settling point (also influenced by the environment).

11-3 What cultural and situational factors influence hunger?

Hunger also reflects our memory of when we last ate and our expectation of when we should eat again. Humans as a species prefer certain tastes (such as sweet and salty), but our individual preferences are also influenced by conditioning, culture, and situation. Some taste preferences, such as the avoidance of new foods, or of foods that have made us ill, have survival value.

11-4 What factors predispose some people to become and remain obese?

Genes and environment interact to produce obesity. Obesity correlates with depression, especially among women. Twin and adoption studies indicate that body weight is also genetically influenced. Environmental influences include lack of exercise, an abundance of high-calorie food, and social influence.

Those wishing to lose weight are advised to make a lifelong change in habits: Get enough sleep; boost energy expenditure through exercise; limit variety and minimize exposure to tempting food cues; eat healthy foods and reduce portion sizes; space meals throughout the day; beware of the binge; monitor eating during social events; forgive the occasional lapse; and connect to a support group.

Sexual Motivation

11-5 How do hormones influence human sexual motivation?

For all but the tiny fraction of us considered *asexual*, dating and mating become a high priority from puberty on. The female *estrogen* and male *testosterone* hormones influence human sexual behavior less directly than they influence sexual behavior in other species. Women's sexuality is more responsive to testosterone level than to estrogen level. Short-term shifts in testosterone level are normal in men, partly in response to stimulation.

11-6 What is the human sexual response cycle, and how do sexual dysfunctions and paraphilias differ?

William Masters and Virginia Johnson described four stages in the human *sexual response cycle*: excitement, plateau, orgasm (which seems to involve similar feelings and brain activity in males and females), and resolution. During the resolution phase, males experience a *refractory period* in which renewed arousal and orgasm are impossible.

Sexual dysfunctions are problems that consistently impair sexual arousal or functioning. They include *erectile disorder* and *female orgasmic disorder*, and can often be successfully treated by behaviorally oriented therapy or drug therapy. *Paraphilias* are conditions, which may be classified as disorders, in which sexual arousal is related to nonhuman objects, the suffering of self or others, and/or nonconsenting persons.

11-7 How can sexually transmitted infections be prevented?

Safe-sex practices help prevent sexually transmitted infections (STIs). Condoms are especially effective in preventing transmission of HIV, the virus that causes AIDS. A

vaccination administered before sexual contact can prevent most human papilloma virus infections.

11-8 How do external and imagined stimuli contribute to sexual arousal?

External stimuli can trigger sexual arousal in both men and women. In experiments, depictions of sexual coercion have increased acceptance of rape. Men respond more specifically to sexual depictions involving their preferred sex. Sexually explicit material may lead people to perceive their partners as comparatively less appealing and to devalue their relationships. Imagined stimuli (dreams and fantasies) also influence sexual arousal.

11-9 What factors influence teenagers' sexual behaviors and use of contraceptives?

Rates of teen intercourse vary from culture to culture and era to era. Factors contributing to teen pregnancy include minimal communication about birth control with parents, partners, and peers; guilt related to sexual activity; alcohol use; and mass media norms of unprotected and impulsive sexuality. High intelligence, religious engagement, father presence, and participation in service learning programs have been predictors of teen sexual restraint.

11-10 What has research taught us about sexual orientation?

Sexual orientation is an enduring sexual attraction toward members of one's own sex (homosexual orientation), the other sex (heterosexual orientation), or both sexes (bisexual orientation). About 3 or 4 percent of men and 2 percent of women in Europe and the United States identify as exclusively homosexual, and 3.4 percent of Americans describe themselves as lesbian, gay, bisexual, or transgender. There is no evidence that environmental influences determine sexual orientation. Evidence for biological influences includes the presence of same-sex attraction in many animal species; straight-gay brain differences; higher rates in certain families and in identical twins; exposure to certain hormones during critical periods of prenatal development; and the fraternal birth-order effect.

11-11 Is scientific research on sexual motivation value free?

Scientific research on sexual motivation does not attempt to define the personal meaning of sex in our lives, but sex research and education are not value free.

Affiliation and Achievement

11-12 What evidence points to our human affiliation need—our need to belong?

Our *need to affiliate* or belong—to feel connected and identified with others—had survival value for our ancestors, which may explain why humans in every society live in groups. Because of their need to belong, people suffer when socially excluded, and they may engage in self-defeating behaviors (performing below their ability) or in antisocial behaviors. Feeling loved activates brain regions associated with reward and safety systems. *Ostracism* is the deliberate exclusion of individuals or groups. Social isolation can put us at risk mentally and physically.

11-13 How does social networking influence us?

We connect with others through social networking, strengthening our relationships with those we already know. When networking, people tend toward increased self-disclosure. People with high *narcissism* are especially active on social networking sites. Working out strategies for self-control and disciplined usage can help people maintain a healthy balance between social connections and school and work performance.

11-14 What is achievement motivation?

Achievement motivation is a desire for significant accomplishment, for mastery of skills or ideas, for control, and for attaining a high standard. Achievements are more closely related to *grit* (passionate dedication to a long-term goal) than to raw ability.

CHAPTER 12

EMOTIONS, STRESS, AND HEALTH

Introduction to Emotion

12-1 How do arousal, expressive behavior, and cognition interact in emotion?

Emotions are psychological responses of the whole organism involving an interplay among physiological arousal, expressive behaviors, and conscious experience.

Theories of emotion generally address two major questions: (1) Does physiological arousal come before or after emotional feelings, and (2) how do feeling and cognition interact? The *James-Lange theory* maintains that emotional feelings follow our body's response to emotion-inducing stimuli. The *Cannon-Bard theory* proposes that our physiological response to an emotion-inducing stimulus occurs at the same time as our subjective feeling of the emotion (one does not cause the other).

12-2 To experience emotions, must we consciously interpret and label them?

The Schachter-Singer *two-factor theory* holds that our emotions have two ingredients, physical arousal and a cognitive label, and the cognitive labels we put on our states of arousal are an essential ingredient of emotion. Lazarus agreed that many important emotions arise from our interpretations or inferences. Zajonc and LeDoux, however, believe that some simple emotional responses occur instantly, not only outside our conscious awareness, but before any cognitive processing occurs. This interplay between emotion and cognition illustrates our dual-track mind.

12-3 What is the link between emotional arousal and the autonomic nervous system? How does arousal affect performance?

The arousal component of emotion is regulated by the autonomic nervous system's sympathetic (arousing) and parasympathetic (calming) divisions. In a crisis, the fight-or-flight response automatically mobilized your body for action.

Arousal affects performance in different ways, depending on the task. Performance peaks at lower levels of arousal for difficult tasks, and at higher levels for easy or well-learned tasks.

12-4 Do different emotions activate different physiological and brain-pattern responses?

Emotions may be similarly arousing, but some subtle physiological responses, such as facial muscle movements, distinguish them. More meaningful differences have been found in activity in some brain pathways and cortical areas.

12-5 How effective are polygraphs in using body states to detect lies?

Polygraphs, which measure several physiological indicators of emotion, are not accurate enough to justify widespread use in business and law enforcement. The use of guilty knowledge questions and new forms of technology may produce better indications of lying.

Expressing Emotion

12-6 How do we communicate nonverbally?

Much of our communication is through body movements, facial expressions, and voice tones. Even seconds-long filmed slices of behavior can reveal feelings.

12-7 Do the genders differ in their ability to communicate nonverbally?

Women tend to read emotional cues more easily and to be more empathic. Their faces also express more emotion.

12-8 Do gestures and facial expressions mean the same thing in all cultures?

The meaning of gestures varies with culture, but facial expressions, such as those of happiness and sadness, are common the world over. Cultures also differ in the amount of emotion they express.

12-9 How do our facial expressions influence our feelings?

Research on the *facial feedback effect* shows that our facial expressions can trigger emotional feelings and signal our body to respond accordingly. We also mimic others' expressions, which helps us empathize. A similar *behavior feedback effect* is the tendency of behavior to influence our own and others' thoughts, feelings, and actions.

Experiencing Emotion

12-10 What are some basic emotions, and what two dimensions help differentiate them?

Carroll Izard's 10 basic emotions are joy, interest-excitement, surprise, sadness, anger, disgust, contempt, fear, shame, and guilt.

Two dimensions that help differentiate emotions are positive-versus-negative valence and low-versus-high arousal.

12-11 What are the causes and consequences of anger?

Anger is most often evoked by misdeeds that we interpret as willful, unjustified, and avoidable. But smaller frustrations and blameless annoyances can also trigger anger. Chronic hostility is one of the negative emotions linked to heart disease. Emotional *catharsis* may be temporarily calming, but in the long run it does not reduce anger. Expressing anger can make us angrier. Controlled assertions of feelings may resolve conflicts, and forgiveness may rid us of angry feelings.

12-12 What is the *feel-good, do-good phenomenon*, and what is the focus of positive psychology research?

A good mood brightens people's perceptions of the world. *Subjective well-being* is your perception of being happy or satisfied with life. Happy people tend to be healthy, energized, and satisfied with life. They also are more willing to help others (the *feel-good, do-good phenomenon*).

Positive psychologists use scientific methods to study human flourishing, including topics such as positive emotions, positive health, positive neuroscience, and positive education. The three pillars of positive psychology are positive well-being; positive character; and positive groups, communities, and cultures.

12-13 How do time, wealth, adaptation, and comparison affect our happiness levels?

The moods triggered by good or bad events seldom last beyond that day. Even significant good events, such as sudden wealth, seldom increase happiness for long. Happiness is relative to our own experiences (the *adaptation-level phenomenon*) and to others' success (the *relative deprivation* principle).

12-14 What are some predictors of happiness?

Some individuals, because of their genetic predispositions and personal histories, are happier than others. Cultures, which vary in the traits they value and the behaviors they expect and reward, also influence personal levels of happiness. Researchers have found that happy people tend to have high self-esteem (in individualist countries); be optimistic, outgoing, and agreeable; have close friendships or a satisfying marriage; have work and leisure that engage their skills; have an active religious faith (particularly in more religious cultures); and sleep well and exercise.

Stress and Illness

12-15 What events provoke stress responses, and how do we respond and adapt to stress?

Stress is the process by which we appraise and respond to stressors (catastrophic events, significant life changes, and daily hassles) that challenge or threaten us. Walter Cannon

viewed the stress response as a “fight-or-flight” system. Hans Selye proposed a general three-phase (alarm-resistance-exhaustion) *general adaptation syndrome (GAS)*. Facing stress, women may have a *tend-and-befriend* response; men may withdraw socially, turn to alcohol, or become aggressive.

12-16 How does stress make us more vulnerable to disease?

Health psychology is a subfield of psychology that provides psychology’s contribution to behavioral medicine. *Psychoneuroimmunologists* study mind-body interactions, including stress-related physical illnesses, such as hypertension and some headaches. Stress diverts energy from the immune system, inhibiting the activities of its B and T lymphocytes, macrophages, and NK cells. Stress does not cause diseases such as AIDS and cancer, but by altering our immune functioning it may make us more vulnerable to them and influence their progression.

12-17 Why are some of us more prone than others to coronary heart disease?

Coronary heart disease, the United States’ number one cause of death, has been linked with the reactive, anger-prone *Type A* personality. Compared with relaxed, easygoing *Type B* personalities, Type A people secrete more stress hormones. Chronic stress also contributes to persistent inflammation, which heightens the risk of clogged arteries and depression.

Health and Coping

12-18 In what two ways do people try to alleviate stress?

We use *problem-focused coping* to change the stressor or the way we interact with it. We use *emotion-focused coping* to avoid or ignore stressors and attend to emotional needs related to stress reactions.

12-19 How does a perceived lack of control affect health?

A perceived lack of control provokes an outpouring of hormones that put people’s health at risk. Being unable to avoid repeated aversive events can lead to *learned helplessness*. People who perceive an *internal locus of control* achieve more, enjoy better health, and are happier than those who perceive an *external locus of control*.

12-20 How can our self-control be depleted, and why is it important to build this strength?

Exercising willpower temporarily depletes the mental energy needed for *self-control* on other tasks. Self-control requires attention and energy, but it predicts good adjustment, better grades, and social success.

12-21 How does an optimistic outlook affect health and longevity?

Studies of people with an optimistic outlook show that their immune system is stronger, their blood pressure does not increase as sharply in response to stress, their recovery from heart bypass surgery is faster, and their life expectancy is longer, compared with their pessimistic counterparts.

12-22 How does social support promote good health?

Social support promotes health by calming us, reducing blood pressure and stress hormones, and by fostering stronger immune functioning.

12-23 How effective is aerobic exercise as a way to manage stress and improve well-being?

Aerobic exercise is sustained, oxygen-consuming activity that increases heart and lung fitness. It increases arousal, leads to muscle relaxation and sounder sleep, triggers the production of neurotransmitters, and enhances self-image. It can relieve depression and, in later life, is associated with better cognitive functioning and longer life.

12-24 In what ways might relaxation and meditation influence stress and health?

Relaxation and meditation have been shown to reduce stress by relaxing muscles, lowering blood pressure, improving immune functioning, and lessening anxiety and depression. Massage therapy also relaxes muscles and reduces depression.

12-25 What is the faith factor, and what are some possible explanations for the link between faith and health?

The faith factor is the finding that religiously active people tend to live longer than those who are not religiously active. Possible explanations may include the effect of intervening variables, such as the healthy behaviors, social support, or positive emotions often found among people who regularly attend religious services.

CHAPTER 13

SOCIAL PSYCHOLOGY

Social Thinking

13-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

Social psychologists use scientific methods to study how people think about, influence, and relate to one another. They study the social influences that explain why the same person will act differently in different situations. When explaining others' behavior, we may—especially if we come from an individualist Western culture—commit the *fundamental attribution error*, by underestimating the influence of the situation and overestimating the effects of stable, enduring traits. When explaining our own behavior, we more readily attribute it to the influence of the situation.

13-2 How do attitudes and actions interact?

Attitudes are feelings, often influenced by our beliefs, that predispose us to respond in certain ways. *Peripheral route persuasion* uses incidental cues (such as celebrity endorsement) to try to produce fast but relatively thoughtless changes in attitudes. *Central route persuasion* offers evidence and arguments to trigger thoughtful responses. When other influences are minimal, attitudes that are stable, specific, and easily recalled can affect our actions.

Actions can modify attitudes, as in the *foot-in-the-door phenomenon* (complying with a large request after having agreed to a small request) and *role playing* (acting a social part by following guidelines for expected behavior). When our attitudes don't fit with our actions, *cognitive dissonance theory* suggests that we will reduce tension by changing our attitudes to match our actions.

Social Influence

13-3 What is automatic mimicry, and how do conformity experiments reveal the power of social influence?

Automatic mimicry (the chameleon effect)—our tendency to unconsciously imitate others' expressions, postures, and voice tones—is a form of *conformity*.

Solomon Asch and others have found that we are most likely to adjust our behavior or thinking to coincide with a group standard when (a) we feel incompetent or insecure, (b) our group has at least three people, (c) everyone else agrees, (d) we admire the group's status and attractiveness, (e) we have not already committed to another response, (f) we know we are being observed, and (g) our culture encourages respect for social standards. We may conform to gain approval (*normative social influence*) or because we are willing to accept others' opinions as new information (*informational social influence*).

13-4 What did Milgram's obedience experiments teach us about the power of social influence?

Stanley Milgram's experiments—in which people obeyed orders even when they thought they were harming another person—demonstrated that strong social influences can make ordinary people conform to falsehoods or give in to cruelty. Obedience was highest when (a) the person giving orders was nearby and was perceived as a legitimate authority figure; (b) the research was supported by a prestigious institution; (c) the victim was depersonalized or at a distance; and (d) there were no role models for defiance.

13-5 How is our behavior affected by the presence of others?

In *social facilitation*, the mere presence of others arouses us, improving our performance on easy or well-learned tasks but decreasing it on difficult ones. In *social loafing*, participating in a group project makes us feel less responsible, and we may free ride on others' efforts. When the presence of others both arouses us and makes us feel anonymous, we may experience *deindividuation*—loss of self-awareness and self-restraint.

13-6 What are *group polarization* and *groupthink*, and how much power do we have as individuals?

In *group polarization*, group discussions with like-minded others strengthen members' prevailing beliefs and attitudes. Internet communication magnifies this effect, for better and for worse. *Groupthink* is driven by a desire for harmony within a decision-making group, overriding realistic appraisal of alternatives.

The power of the individual and the power of the situation interact. A small minority that consistently expresses its views may sway the majority.

Antisocial Relations

13-7 What is *prejudice*? What are its social and emotional roots?

Prejudice is an unjustifiable, usually negative, attitude toward a group and its members. Prejudice's three components are beliefs (often *stereotypes*), emotions, and predispositions to action (*discrimination*). Overt prejudice in North America has decreased over time, but implicit prejudice—an automatic, unthinking attitude—continues.

The social roots of prejudice include social inequalities and divisions. Higher-status groups often justify their privileged position with the *just-world phenomenon*. We tend to favor our own group (*ingroup bias*) as we divide ourselves into “us” (the *ingroup*) and “them” (the *outgroup*).

Prejudice can also be a tool for protecting our emotional well-being, as when we focus our anger by blaming events on a *scapegoat*.

13-8 What are the cognitive roots of prejudice?

The cognitive roots of prejudice grow from our natural ways of processing information: forming categories, remembering vivid cases, and believing that the world is just and that our own and our culture's ways of doing things are the right ways.

13-9 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

In psychology's more specific meaning, *aggression* is any act intended to harm someone physically or emotionally. Biology influences our threshold for aggressive behaviors at three levels: genetic (inherited traits), neural (activity in key brain areas), and biochemical (such as alcohol or excess testosterone in the bloodstream). Aggression is a complex behavior resulting from the interaction of biology and experience.

13-10 What psychological and social-cultural factors may trigger aggressive behavior?

Frustration (*frustration-aggression principle*), previous reinforcement for aggressive behavior, observing an aggressive role model, and poor self-control can all contribute to

aggression. Media portrayals of violence provide *social scripts* that children learn to follow. Viewing sexual violence contributes to greater aggression toward women. Playing violent video games increases aggressive thoughts, emotions, and behaviors.

Prosocial Relations

13-11 Why do we befriend or fall in love with some people but not others?

Proximity (geographical nearness) increases liking, in part because of the *mere exposure effect*—exposure to novel stimuli increases liking of those stimuli. Physical attractiveness increases social opportunities and improves the way we are perceived. Similarity of attitudes and interests greatly increases liking, especially as relationships develop. We also like those who like us.

13-12 How does romantic love typically change as time passes?

Intimate love relationships start with *passionate love*—an intensely aroused state. Over time, the strong affection of *companionate love* may develop, especially if enhanced by an *equitable* relationship and by intimate *self-disclosure*.

13-13 When are people most—and least—likely to help?

Altruism is unselfish regard for the well-being of others. We are most likely to help when we (a) notice an incident, (b) interpret it as an emergency, and (c) assume responsibility for helping. Other factors, including our mood and our similarity to the victim, also affect our willingness to help. We are least likely to help if other bystanders are present (the *bystander effect*).

13-14 How do social exchange theory and social norms explain helping behavior?

Social exchange theory is the view that we help others because it is in our own self-interest; in this view, the goal of social behavior is maximizing personal benefits and minimizing costs. Others believe that helping results from socialization, in which we are taught guidelines for expected behaviors in social situations, such as the *reciprocity norm* and the *social-responsibility norm*.

13-15 How do social traps and mirror-image perceptions fuel social conflict?

A *conflict* is a perceived incompatibility of actions, goals, or ideas. *Social traps* are situations in which people in conflict pursue their own individual self-interest, harming the collective well-being. Individuals and cultures in conflict also tend to form *mirror-image perceptions*: Each party views the opponent as untrustworthy and evil-intentioned, and itself as an ethical, peaceful victim. Perceptions can become *self-fulfilling prophecies*.

13-16 How can we transform feelings of prejudice, aggression, and conflict into attitudes that promote peace?

Peace can result when individuals or groups work together to achieve *superordinate* (shared) *goals*. Research indicates that four processes—contact, cooperation, communication, and conciliation—help promote peace.

CHAPTER 14

PERSONALITY

Introduction to Personality and Psychodynamic Theories

14-1 What historically significant and current theories inform our understanding of personality?

Personality is an individual's characteristic pattern of thinking, feeling, and acting. *Psychodynamic theories* view personality from the perspective that behavior is a dynamic

interaction between the conscious and unconscious mind. These theories trace their origin to Sigmund Freud's theory of *psychoanalysis*. The humanistic approach focused on our inner capacities for growth and self-fulfillment. Trait theories examine characteristic patterns of behavior (traits). Social-cognitive theories explore the interaction between people's traits (including their thinking) and their social context.

14-2 How did Sigmund Freud's treatment of psychological disorders lead to his view of the unconscious mind?

In treating patients whose disorders had no clear physical explanation, Freud concluded that these problems reflected unacceptable thoughts and feelings, hidden away in the *unconscious* mind. To explore this hidden part of a patient's mind, Freud used *free association* and dream analysis.

14-3 What was Freud's view of personality?

Freud believed that personality results from conflict arising from the interaction among the mind's three systems: the *id* (pleasure-seeking impulses), *ego* (reality-oriented executive), and *superego* (internalized set of ideals, or conscience).

14-4 What developmental stages did Freud propose?

He believed children pass through five *psychosexual stages* (oral, anal, phallic, latency, and genital). Unresolved conflicts at any stage can leave a person's pleasure-seeking impulses *fixated* (stalled) at that stage.

14-5 How did Freud think people defended themselves against anxiety?

For Freud, anxiety was the product of tensions between the demands of the *id* and *superego*. The *ego* copes by using unconscious *defense mechanisms*, such as *repression*, which he viewed as the basic mechanism underlying and enabling all the others.

14-6 Which of Freud's ideas did his followers accept or reject?

Freud's early followers, the neo-Freudians, accepted many of his ideas. They differed in placing more emphasis on the conscious mind and in stressing social motives more than sex or aggression. Most contemporary psychodynamic theorists and therapists reject Freud's emphasis on sexual motivation. They stress, with support from modern research findings, the view that much of our mental life is unconscious, and they believe that our childhood experiences influence our adult personality and attachment patterns. Many also believe that our species' shared evolutionary history shaped some universal predispositions.

14-7 What are projective tests, how are they used, and what are some criticisms of them?

Projective tests attempt to assess personality by showing people ambiguous stimuli (open to many possible interpretations) and treating their answers as revelations of unconscious motives. One such test, the *Rorschach inkblot test*, has low reliability and validity except in a few areas, such as hostility and anxiety.

14-8 How do contemporary psychologists view Freud's psychoanalysis?

They give Freud credit for drawing attention to the vast unconscious, to the struggle to cope with our sexuality, to the conflict between biological impulses and social restraints, and for some forms of defense mechanisms (false consensus effect/projection; reaction formation) and unconscious *terror-management* defenses. But his concept of repression, and his view of the unconscious as a collection of repressed and unacceptable thoughts, wishes, feelings, and memories, cannot survive scientific scrutiny. Freud offered after-the-fact explanations, which are hard to test scientifically. Research does not support many of Freud's specific ideas, such as the view that development is fixed in childhood. (We now know it is lifelong.)

14-9 How has modern research developed our understanding of the unconscious?

Current research confirms that we do not have full access to all that goes on in our mind, but the current view of the unconscious is that it is a separate and parallel track of information processing that occurs outside our awareness. This processing includes schemas that control our perceptions; priming; implicit memories of learned skills; instantly activated emotions; and stereotypes that filter our information processing of others' traits and characteristics.

Humanistic Theories and Trait Theories

14-10 How did humanistic psychologists view personality, and what was their goal in studying personality?

The *humanistic* psychologists' view of personality focused on the potential for healthy personal growth and people's striving for self-determination and self-realization. Abraham Maslow proposed that human motivations form a hierarchy of needs; if basic needs are fulfilled, people will strive toward *self-actualization* and self-transcendence. Carl Rogers believed that the ingredients of a growth-promoting environment are genuineness, acceptance (including *unconditional positive regard*), and empathy. *Self-concept* was a central feature of personality for both Maslow and Rogers.

14-11 How did humanistic psychologists assess a person's sense of self?

Some rejected any standardized assessments and relied on interviews and conversations. Rogers sometimes used questionnaires in which people described their ideal and actual selves, which he later used to judge progress during therapy.

14-12 How have humanistic theories influenced psychology? What criticisms have they faced?

Humanistic psychology helped renew interest in the concept of self. Critics have said that humanistic psychology's concepts were vague and subjective, its values self-centered, and its assumptions naively optimistic.

14-13 How do psychologists use traits to describe personality?

Trait theorists see personality as a stable and enduring pattern of behavior. They describe our differences rather than trying to explain them. Using factor analysis, they identify clusters of behavior tendencies that occur together. Genetic predispositions influence many traits.

14-14 What are some common misunderstandings about introversion? Does extraversion lead to greater success than introversion?

Introversion is often misunderstood as shyness, but introverted people often simply seek low levels of stimulation from their environment. Introversion is also sometimes thought to be a barrier to success, but in fact introverts often experience great achievement, even in sales, through characteristics such as their superior listening skills.

14-15 What are personality inventories, and what are their strengths and weaknesses as trait-assessment tools?

Personality inventories (such as the *MMPI*) are questionnaires on which people respond to items designed to gauge a wide range of feelings and behaviors. Test items are *empirically derived*, and the tests are objectively scored. But people can fake their answers to create a good impression, and the ease of computerized testing may lead to misuse of the tests.

14-16 Which traits seem to provide the most useful information about personality variation?

The Big Five personality factors—conscientiousness, agreeableness, neuroticism, openness, and extraversion (CANOE)—currently offer the clearest picture of personality. These factors are quite stable and appear to be found in all cultures.

14-17 Does research support the consistency of personality traits over time and across situations?

A person's average traits persist over time and are predictable over many different situations. But traits cannot predict behavior in any one particular situation.

Social-Cognitive Theories and the Self

14-18 How do social-cognitive theorists view personality development, and how do they explore behavior?

Albert Bandura first proposed the *social-cognitive perspective*, which emphasizes the interaction of our traits with our situations. Social-cognitive researchers apply principles of learning, cognition, and social behavior to personality. *Reciprocal determinism* is a term describing the interaction and mutual influence of behavior, internal personal factors, and environmental factors.

14-19 What criticisms have social-cognitive theorists faced?

Social-cognitive theorists build on well-established concepts of learning and cognition. They tend to believe that the best way to predict someone's behavior in a given situation is to observe that person's behavior in similar situations. They have been faulted for underemphasizing the importance of unconscious motives, emotions, and biologically influenced traits.

14-20 Why has psychology generated so much research on the self? How important is self-esteem to psychology and to human well-being?

The *self* is the center of personality, organizing our thoughts, feelings, and actions. Considering possible selves helps motivate us toward positive development, but focusing too intensely on ourselves can lead to the *spotlight effect*.

Self-esteem is our feeling of self-worth; *self-efficacy* is our sense of competence on a task. High self-esteem correlates with less pressure to conform, with persistence at difficult tasks, and with happiness. But the direction of the correlation is not clear. Psychologists caution against unrealistically promoting children's feelings of self-worth. It's better to reward their achievements, which leads to feelings of competence.

14-21 How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

Excessive optimism can lead to complacency and prevent us from seeing real risks, while blindness to one's own incompetence may lead us to make the same mistakes repeatedly. *Self-serving bias* is our tendency to perceive ourselves favorably, as when viewing ourselves as better than average or when accepting credit for our successes but not blame for our failures. *Narcissism* is excessive self-love and self-absorption. Defensive self-esteem is fragile, focuses on sustaining itself, and views failure or criticism as a threat. Secure self-esteem enables us to feel accepted for who we are.

CHAPTER 15

PSYCHOLOGICAL DISORDERS

Introduction to Psychological Disorders

15-1 How should we draw the line between normality and disorder?

According to psychologists and psychiatrists, *psychological disorders* are marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior.

15-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The *medical model* assumes that psychological disorders are mental illnesses with physical causes that can be diagnosed, treated, and, in most cases, cured through therapy, sometimes in a hospital. The biopsychosocial perspective assumes that three sets of influences—biological (evolution, genetics, brain structure and chemistry), psychological (stress, trauma, learned helplessness, mood-related perceptions and memories), and social and cultural circumstances (roles, expectations, definitions of “normality” and “disorder”)—interact to produce specific psychological disorders. *Epigenetics* also informs our understanding of disorders.

15-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

The American Psychiatric Association’s DSM-5 (*Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition) contains diagnostic labels and descriptions that provide a common language and shared concepts for communication and research. Most U.S. health insurance organizations require a DSM diagnosis before paying for treatment.

Some critics believe the DSM editions have become too detailed and extensive. Others view DSM diagnoses as arbitrary labels that create preconceptions, which bias perceptions of the labeled person’s past and present behavior.

15-4 Why is there controversy over attention-deficit/hyperactivity disorder?

A child (or, less commonly, an adult) who displays extreme inattention and/or hyperactivity and impulsivity may be diagnosed with *attention-deficit/hyperactivity disorder (ADHD)* and treated with medication and other therapy. The controversy centers on whether the growing number of ADHD cases reflects overdiagnosis or increased awareness of the disorder. Long-term effects of stimulant-drug treatment for ADHD are not yet known.

15-5 Do psychological disorders predict violent behavior?

Mental disorders seldom lead to violence, but when they do, they raise moral and ethical questions about whether society should hold people with disorders responsible for their violent actions. Most people with disorders are nonviolent and are more likely to be victims than attackers.

15-6 How many people have, or have had, a psychological disorder? Is poverty a risk factor?

Psychological disorder rates vary, depending on the time and place of the survey. In one multinational survey, rates for any disorder ranged from less than 5 percent (Shanghai) to more than 25 percent (the United States). Poverty is a risk factor: Conditions and experiences associated with poverty contribute to the development of psychological disorders. But some disorders, such as schizophrenia, can drive people into poverty.

Anxiety Disorders, OCD, and PTSD

15-7 How do generalized anxiety disorder, panic disorder, and phobias differ?

Anxious feelings and behaviors are classified as an *anxiety disorder* only when they form a pattern of distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. People with *generalized anxiety disorder* feel persistently and uncontrollably tense and apprehensive, for no apparent reason. In the more extreme *panic disorder*, anxiety escalates into periodic episodes of intense dread. Those with a *phobia* may be irrationally afraid of a specific object, activity, or situation. Two other disorders (OCD and PTSD) involve anxiety but are classified separately from the anxiety disorders.

15-8 What is OCD?

Persistent and repetitive thoughts (obsessions), actions (compulsions), or both characterize *obsessive-compulsive disorder (OCD)*.

15-9 What is PTSD?

Symptoms of *posttraumatic stress disorder (PTSD)* include four or more weeks of haunting memories, nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or sleep problems following some traumatic experience.

15-10 How do conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD?

The learning perspective views anxiety disorders, OCD, and PTSD as products of fear conditioning, stimulus generalization, fearful-behavior reinforcement, and observational learning of others' fears and cognitions (interpretations, irrational beliefs, and hypervigilance). The biological perspective considers the role that fears of life-threatening animals, objects, or situations played in natural selection and evolution; genetic predispositions for high levels of emotional reactivity and neurotransmitter production; and abnormal responses in the brain's fear circuits.

Depressive Disorders and Bipolar Disorder

15-11 How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

A person with *major depressive disorder* experiences two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure. Persistent depressive disorder includes a mildly depressed mood more often than not for at least two years, along with at least two other symptoms. A person with the less common condition of *bipolar disorder* experiences not only depression but also *mania*—episodes of hyperactive and wildly optimistic, impulsive behavior.

15-12 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

The biological perspective on depressive disorders and bipolar disorder focuses on genetic predispositions and on abnormalities in brain structures and function (including those found in neurotransmitter systems). The social-cognitive perspective views depression as an ongoing cycle of stressful experiences (interpreted through negative beliefs, attributions, and memories) leading to negative moods and actions and fueling new stressful experiences.

15-13 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

Suicide rates differ by nation, race, gender, age group, income, religious involvement, marital status, and (for gay and lesbian youth, for example) social support structure. Those with depression are more at risk for suicide than others are, but social suggestion, health status, and economic and social frustration are also contributing factors. Environmental barriers (such as jump barriers) are effective in preventing suicides. Forewarnings of suicide may include verbal hints, giving away possessions, withdrawal, preoccupation with death, and discussing one's own suicide.

Nonsuicidal self-injury (NSSI) does not usually lead to suicide but may escalate to suicidal thoughts and acts if untreated. People who engage in NSSI do not tolerate stress well and tend to be self-critical, with poor communication and problem-solving skills.

Schizophrenia

15-14 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Symptoms of *schizophrenia* include disturbed perceptions, disorganized thinking and speech, and diminished, inappropriate emotions. *Delusions* are false beliefs; hallucinations are sensory experiences without sensory stimulation. Schizophrenia symptoms may be positive (the presence of inappropriate behaviors) or negative (the absence of appropriate behaviors).

15-15 How do chronic and acute schizophrenia differ?

Schizophrenia typically strikes during late adolescence, affects men slightly more than women, and seems to occur in all cultures. In *chronic* (or process) schizophrenia, the disorder develops gradually and recovery is doubtful. In *acute* (or reactive) schizophrenia, the onset is sudden, in reaction to stress, and the prospects for recovery are brighter.

15-16 What brain abnormalities are associated with schizophrenia?

People with schizophrenia have increased dopamine receptors, which may intensify brain signals, creating positive symptoms such as hallucinations and paranoia. Brain abnormalities associated with schizophrenia include enlarged, fluid-filled cerebral cavities and corresponding decreases in the cortex. Brain scans reveal abnormal activity in the frontal lobes, thalamus, and amygdala. Interacting malfunctions in multiple brain regions and their connections may produce schizophrenia's symptoms.

15-17 What prenatal events are associated with increased risk of developing schizophrenia?

Possible contributing factors include viral infections or famine conditions during the mother's pregnancy; low weight or oxygen deprivation at birth; and maternal diabetes or older paternal age.

15-18 Do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Twin and adoption studies indicate that the predisposition to schizophrenia is inherited. Multiple genes probably interact to produce schizophrenia. No environmental causes invariably produce schizophrenia, but environmental events (such as prenatal viruses or maternal stress) may "turn on" genes for this disorder in those who are predisposed to it.

Possible early warning signs of later development of schizophrenia include both biological factors (a mother with severe and long-lasting schizophrenia; oxygen deprivation and low weight at birth; separation from parents; short attention span and poor muscle coordination) and psychological factors (disruptive or withdrawn behavior; emotional unpredictability; poor peer relations and solo play).

Dissociative, Personality, and Eating Disorders

15-19 What are dissociative disorders, and why are they controversial?

Dissociative disorders are conditions in which conscious awareness seems to become separated from previous memories, thoughts, and feelings. Skeptics note that *dissociative identity disorder*, formerly known as multiple personality disorder, increased dramatically in the late twentieth century; is rarely found outside North America; and may reflect role playing by people who are vulnerable to therapists' suggestions. Others view this disorder as a manifestation of feelings of anxiety, or as a response learned when behaviors are reinforced by anxiety-reduction.

15-20 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

Personality disorders are disruptive, inflexible, and enduring behavior patterns that impair social functioning. This disorder forms three clusters, characterized by (1) anxiety, (2) eccentric or odd behaviors, and (3) dramatic or impulsive behaviors.

Antisocial personality disorder (one of those in the third cluster) is characterized by a lack of conscience and, sometimes, by aggressive and fearless behavior. Genetic predispositions may interact with the environment to produce the altered brain activity associated with antisocial personality disorder.

15-21 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

In those with eating disorders (most often women or gay men), psychological factors can overwhelm the body's tendency to maintain a normal weight. Despite being significantly underweight, people with *anorexia nervosa* (usually adolescent females) continue to diet and exercise excessively because they view themselves as fat. Those with *bulimia nervosa* (usually females in their teens and twenties) secretly binge and then compensate by purging, fasting, or excessive exercise. Those with *binge-eating disorder* binge but do not follow with purging, fasting, and exercise. Cultural pressures, low self-esteem, and negative emotions interact with stressful life experiences and genetics to produce eating disorders.

CHAPTER 16

THERAPY

Introduction to Therapy and the Psychological Therapies

16-1 How do *psychotherapy* and the *biomedical therapies* differ?

Psychotherapy is treatment involving psychological techniques; it consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. The major psychotherapies derive from psychology's psychodynamic, humanistic, behavioral, and cognitive perspectives. *Biomedical therapy* treats psychological disorders with medications or procedures that act directly on a patient's physiology. An *eclectic approach* combines techniques from various forms of therapy.

16-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

Through *psychoanalysis*, Sigmund Freud tried to give people self-insight and relief from their disorders by bringing anxiety-laden feelings and thoughts into conscious awareness. Psychoanalytic techniques included using free association and *interpretation* of instances of *resistance* and *transference*. *Psychodynamic therapy* has been influenced by traditional psychoanalysis but differs from it in many ways, including the lack of belief in id, ego, and superego. This contemporary therapy is briefer, less expensive, and more focused on helping the client find relief from current symptoms. Psychodynamic therapists help clients understand how past relationships create themes that may be acted out in present relationships. Interpersonal therapy is a brief 12- to 16-session form of psychodynamic therapy that has been effective in treating depression.

16-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?

Both psychoanalytic and humanistic therapists are *insight therapies*—they attempt to improve functioning by increasing clients' awareness of motives and defenses. Humanistic

therapy's goals have included helping clients grow in self-awareness and self-acceptance; promoting personal growth rather than curing illness; helping clients take responsibility for their own growth; focusing on conscious thoughts rather than unconscious motivations; and seeing the present and future as more important than the past.

Carl Rogers' *client-centered therapy* proposed that therapists' most important contributions are to function as a psychological mirror through *active listening* and to provide a growth-fostering environment of *unconditional positive regard*, characterized by genuineness, acceptance, and empathy.

16-4 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

Behavior therapies are not insight therapies. Their goal is to apply learning principles to modify problem behaviors.

Classical conditioning techniques, including *exposure therapies* (such as *systematic desensitization* or *virtual reality exposure therapy*) and *aversive conditioning*, attempt to change behaviors through *counterconditioning*—evoking new responses to old stimuli that trigger unwanted behaviors.

16-5 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

Operant conditioning operates under the premise that voluntary behaviors are strongly influenced by their consequences. Therapy based on operant conditioning principles uses behavior modification techniques to change unwanted behaviors through positively reinforcing desired behaviors and ignoring or punishing undesirable behaviors.

Critics maintain that (1) techniques such as those used in *token economies* may produce behavior changes that disappear when rewards end, and (2) deciding which behaviors should change is authoritarian and unethical. Proponents argue that treatment with positive rewards is more humane than punishing people or institutionalizing them for undesired behaviors.

16-6 What are the goals and techniques of cognitive therapy and of cognitive-behavioral therapy?

The *cognitive therapies*, such as Aaron Beck's cognitive therapy for depression, assume that our thinking influences our feelings, and that the therapist's role is to change clients' self-defeating thinking by training them to view themselves in more positive ways. The widely researched and practiced *cognitive-behavioral therapy* (CBT) combines cognitive therapy and behavior therapy by helping clients regularly act out their new ways of thinking and talking in their everyday life.

16-7 What are the aims and benefits of group and family therapies?

Group therapy sessions can help more people and costs less per person than individual therapy would. Clients may benefit from exploring feelings and developing social skills in a group situation, from learning that others have similar problems, and from getting feedback on new ways of behaving. *Family therapy* views a family as an interactive system and attempts to help members discover the roles they play and to learn to communicate more openly and directly.

Evaluating Psychotherapies

16-8 Does psychotherapy work? How can we know?

Clients' and therapists' positive testimonials cannot prove that psychotherapy is actually effective, and the placebo effect makes it difficult to judge whether improvement occurred because of the treatment.

Using *meta-analyses* to statistically combine the results of hundreds of randomized psychotherapy outcome studies, researchers have found that those not undergoing treatment often improve, but those undergoing psychotherapy are more likely to improve more quickly, and with less chance of relapse.

16-9 Are some psychotherapies more effective than others for specific disorders?

No one type of psychotherapy is generally superior to all others. Therapy is most effective for those with clear-cut, specific problems. Some therapies—such as behavior conditioning for treating phobias and compulsions—are more effective for specific disorders. Psychodynamic therapy has been effective for depression and anxiety, and cognitive and cognitive-behavioral therapies have been effective in coping with anxiety, posttraumatic stress disorder, and depression. *Evidence-based practice* integrates the best available research with clinicians' expertise and patients' characteristics, preferences, and circumstances.

16-10 How do alternative therapies fare under scientific scrutiny?

Abnormal states tend to return to normal on their own, and the placebo effect can create the impression that a treatment has been effective. These two tendencies complicate assessments of alternative therapies (nontraditional therapies that claim to cure certain ailments). Eye movement desensitization and reprocessing (EMDR) has shown some effectiveness—not from the eye movement but rather from the exposure therapy nature of the treatments. Light exposure therapy does seem to relieve depression symptoms for those with a seasonal pattern of major depressive disorder by activating a brain region that influences arousal and hormones.

16-11 What three elements are shared by all forms of psychotherapy?

All psychotherapies offer new hope for demoralized people; a fresh perspective; and (if the therapist is effective) an empathic, trusting, and caring relationship. The emotional bond of trust and understanding between therapist and client—the *therapeutic alliance*—is an important element in effective therapy.

16-12 How do culture and values influence the therapist-client relationship?

Therapists differ in the values that influence their goals in therapy and their views of progress. These differences may create problems if therapists and clients differ in their cultural or religious perspectives.

16-13 What should a person look for when selecting a therapist?

A person seeking therapy may want to ask about the therapist's treatment approach, values, credentials, and fees. An important consideration is whether the therapy seeker feels comfortable and able to establish a bond with the therapist.

Biomedical Therapies and Preventing Psychological Disorders

16-14 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

Psychopharmacology, the study of drug effects on mind and behavior, has helped make drug therapy the most widely used biomedical therapy. *Antipsychotic drugs*, used in treating schizophrenia, block dopamine activity. Side effects may include tardive dyskinesia (with involuntary movements of facial muscles, tongue, and limbs) or increased risk of obesity and diabetes. *Antianxiety drugs*, which depress central nervous system activity, are used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. These drugs can be physically and psychologically addictive. *Antidepressant drugs*, which increase the availability of serotonin and norepinephrine, are used for

depression, with modest effectiveness beyond that of placebo drugs. The antidepressants known as selective serotonin reuptake inhibitors (often called SSRI drugs) are now used to treat other disorders, including strokes and anxiety disorders. Lithium and Depakote are mood stabilizers prescribed for those with bipolar disorder. Studies may use a double-blind procedure to avoid the placebo effect and researcher's bias.

16-15 How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive therapy (ECT), in which a brief electric current is sent through the brain of an anesthetized patient, is an effective, last-resort treatment for severely depressed people who have not responded to other therapy. Newer alternative treatments for depression include *repetitive transcranial magnetic stimulation (rTMS)* and, in preliminary clinical experiments, deep-brain stimulation that calms an overactive brain region linked with negative emotions.

Psychosurgery removes or destroys brain tissue in hopes of modifying behavior. Radical psychosurgical procedures such as *lobotomy* were once popular, but neurosurgeons now rarely perform brain surgery to change behavior or moods. Brain surgery is a last-resort treatment because its effects are irreversible.

16-16 How, by taking care of themselves with a healthy lifestyle, might people find some relief from depression? How does this reflect our being biopsychosocial systems?

Depressed people who undergo a program of aerobic exercise, adequate sleep, light exposure, social engagement, negative-thought reduction, and better nutrition often gain some relief. In our integrated biopsychosocial system, stress affects our body chemistry and health; chemical imbalances can produce depression; and social support and other lifestyle changes can lead to relief of symptoms.

16-17 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

Preventive mental health programs are based on the idea that many psychological disorders could be prevented by changing oppressive, esteem-destroying environments into more benevolent, nurturing environments that foster growth, self-confidence, and *resilience*. Struggling with challenges can lead to *posttraumatic growth*. Community psychologists are often active in preventive mental health programs.

APPENDIX A

PSYCHOLOGY AT WORK

A-1 What is *flow*, and what are the three subfields of industrial-organizational psychology?

Flow is a completely involved, focused state of consciousness with diminished awareness of self and time. It results from fully engaging one's skills. *Industrial-organizational (I/O) psychology's* three subfields are *personnel*, *organizational*, and *human factors psychology*.

A-2 How do personnel psychologists help organizations with employee selection, work placement, and performance appraisal?

Personnel psychologists work with organizations to devise selection methods for new employees; recruit and evaluate applicants; design and evaluate training programs; identify people's strengths; analyze job content; and appraise individual and organizational performance. Unstructured, subjective interviews foster the interviewer illusion; *structured interviews* pinpoint job-relevant strengths and are better predictors of performance. Checklists, graphic rating scales, and behavior rating scales are useful performance appraisal methods.

A-3 What is the role of organizational psychologists?

Organizational psychologists examine influences on worker satisfaction and productivity and facilitate organizational change. Employee satisfaction and engagement tend to correlate with organizational success.

A-4 What are some effective leadership techniques?

Effective leaders harness job-relevant strengths; set specific challenging goals; and choose an appropriate leadership style. Leadership style may be goal-oriented (*task leadership*), group-oriented (*social leadership*), or some combination of the two.

A-5 How do human factors psychologists work to create user-friendly machines and work settings?

Human factors psychologists contribute to human safety and improved design by encouraging developers and designers to consider human perceptual abilities, to avoid the curse of knowledge, and to test users to reveal perception-based problems.

Answers to *Test Yourself* Questions

PROLOGUE

THE STORY OF PSYCHOLOGY

What Is Psychology?

1. Wilhelm Wundt
2. a
3. a
4. b
5. The environment (nurture) has an influence on us, but that influence is constrained by our biology (nature). Nature and nurture interact. People predisposed to be very tall (nature), for example, are unlikely to become Olympic gymnasts, no matter how hard they work (nurture).
6. d
7. psychiatrist
8. c

CHAPTER 1

THINKING CRITICALLY WITH PSYCHOLOGICAL SCIENCE

The Need for Psychological Science

1. Hindsight bias
2. d
3. Critical thinking examines assumptions, appraises the source, discerns hidden values, evaluates evidence, and assesses conclusions. In evaluating a claim in the media, look for any signs of empirical evidence, preferably from several studies. Ask the following questions in your analysis: Are claims based on scientific findings? Have several studies replicated the findings and confirmed them? Are any experts cited? If so, research their background. Are they affiliated with a credible university, college, or institution? Have they conducted or written about scientific research?

Research Strategies: How Psychologists Ask and Answer Questions

4. hypotheses
5. c

6. representative

7. negative

8. scatterplot

9. a

10. Regression toward the mean is a statistical phenomenon describing the tendency of extreme scores or outcomes to return to normal after an unusual event. Without knowing this, we may inaccurately decide the return to normal was a result of our own behavior.

11. a

12. (a) *Alcohol use is associated with violence. (One interpretation: Drinking triggers or unleashes aggressive behavior.)* Perhaps anger triggers drinking, or perhaps the same genes or child-raising practices are predisposing both drinking and aggression. (Here researchers have learned that drinking does indeed trigger aggressive behavior.)

(b) *Educated people live longer, on average, than less-educated people. (One interpretation: Education lengthens life and enhances health.)* Perhaps richer people can afford more education and better health care. (Research supports this conclusion.)

(c) *Teens engaged in team sports are less likely to use drugs, smoke, have sex, carry weapons, and eat junk food than are teens who do not engage in team sports. (One interpretation: Team sports encourage healthy living.)* Perhaps some third factor explains this correlation—teens who use drugs, smoke, have sex, carry weapons, and eat junk food may be “loners” who do not enjoy playing on any team.

(d) *Adolescents who frequently see smoking in movies are more likely to smoke. (One interpretation: Movie stars’ behavior influences impressionable teens.)* Perhaps adolescents who smoke and attend movies frequently have less parental supervision and more access to spending money than other adolescents.

Vision: Sensory and Perceptual Processing

8. wavelength
9. a

10. c
11. c
12. d
13. Your brain constructs this perception of color in two stages. In the first stage, the lemon reflects light energy into your eyes, where it is transformed into neural messages. Three sets of cones, each sensitive to a different light frequency (red, blue, and green) process color. In this case, the light energy stimulates both red-sensitive and green-sensitive cones. In the second stage, opponent-process cells sensitive to paired opposites of color (red/green, yellow/blue, and black/white) evaluate the incoming neural messages as they pass through your optic nerve to the thalamus and visual cortex. When the yellow-sensitive opponent-process cells are stimulated, you identify the lemon as yellow.
14. feature detectors

23. perceptual adaptation

The Nonvisual Senses

24. cochlea
25. The *outer ear* collects sound waves, which are translated into mechanical waves by the *middle ear* and turned into fluid waves in the *inner ear*. The *auditory nerve* then translates the energy into electrical waves and sends them to the brain, which perceives and interprets the sound.
26. Place; frequency
27. c
28. Our experience of pain is influenced by biological factors (such as sensory receptors that detect pressure), psychological factors (such as our focused attention), and social-cultural factors (such as social expectations about tolerance and expression of pain).
29. We have specialized receptors for detecting sweet, salty, sour, bitter, and umami tastes. Being able to detect pleasurable tastes enabled our ancestors to seek out energy- and protein-rich foods. Detecting aversive tastes deterred them from eating toxic substances, increasing their chances of survival.
30. Kinesthesia; vestibular sense

31. Your vestibular sense regulates balance and body positioning through kinesthetic receptors triggered by fluid in your inner ear. Wobbly legs and a spinning world are signs that these receptors are still responding to the ride's turbulence. As your vestibular sense adjusts to solid ground, your balance will be restored.

32. d

33. d

CHAPTER 10

INTELLIGENCE

What Is Intelligence?

- 1. general intelligence (*g*)
- 2. c
- 3. academic; practical; creative
- 4. d

Assessing Intelligence

- 5. d
- 6. c
- 7. reliability

The Dynamics of Intelligence

- 8. Writers' work relies more on *crystallized intelligence*, or accumulated knowledge, which increases with age. For top performance, scientists doing research may need more *fluid intelligence* (speedy and abstract reasoning), which tends to decrease with age.
- 9. c

Genetic and Environmental Influences on Intelligence

- 10. a
- 11. c
- 12. c
- 13. Stereotype threat

CHAPTER 11

WHAT DRIVES US: HUNGER, SEX, FRIENDSHIP, AND ACHIEVEMENT

Basic Motivational Concepts

- 1. b
- 2. a
- 3. incentive
- 4. Arousal
- 5. b
- 6. a

Hunger

- 7. Maslow's hierarchy of needs supports this statement because it addresses the primacy of some motives over others. Once our basic physiological needs are met, safety concerns are addressed next, followed by belongingness and love needs (such as the desire to kiss).
- 8. homeostasis
- 9. c
- 10. glucose; low
- 11. basal metabolic
- 12. d
- 13. Sanjay's plan is problematic. After he gains weight, the extra fat will require less energy to maintain than it did to gain in the first place. Sanjay may have a hard time getting rid of it later, when his metabolism slows down in an effort to retain his body weight.

Sexual Motivation

- 14. b
- 15. b
- 16. Sexual dysfunctions are problems that men and women may have related to sexual arousal and sexual function. Paraphilias are conditions, which may be classified as psychological disorders, in which sexual arousal is associated with nonhuman objects, the suffering of self or others, and/or nonconsenting persons.
- 17. does; doesn't

18. c

- 19. Researchers have found no evidence that any environmental factor (parental relationships, childhood experiences, peer relationships, or dating experiences) influences the development of our sexual orientation.

Affiliation and Achievement

20. c

- 21. Monitor the time spent online, as well as our feelings about that time. Hide distracting online friends. Turn off or put away distracting devices. Consider a social networking fast, and get outside and away from technology regularly.

CHAPTER 12

EMOTIONS, STRESS, AND HEALTH

Introduction to Emotion

- 1. James-Lange
- 2. b
- 3. c
- 4. A polygraph measures physiological changes, such as heart rate and perspiration, that are associated with emotions. Its use as a lie detector is controversial because the measure cannot distinguish between emotions with similar physiology (such as anxiety and guilt).

Expressing Emotion

- 5. facial feedback

Experiencing Emotion

- 6. d
- 7. Positive
- 8. b
- 9. relative deprivation

Stress and Illness

- 10. resistance; exhaustion
- 11. tend; befriend
- 12. b
- 13. d
- 14. c
- 15. Type A individuals frequently experience negative emotions (anger, depression), during which the sympathetic nervous system diverts blood away from the liver. This leaves fat and cholesterol circulating in the bloodstream for deposit near the heart and other organs, increasing the risk of heart disease and other health problems. Thus, Type A individuals actually harm themselves by directing anger at others.
- 16. negative

Health and Coping

- 17. emotion
- 18. b
- 19. internal
- 20. d
- 21. aerobic
- 22. c

CHAPTER 13

SOCIAL PSYCHOLOGY

Social Thinking

- 1. a
- 2. peripheral
- 3. foot-in-the-door
- 4. Cognitive dissonance theory best supports this suggestion. If Jamal acts confident, his behavior will contradict his negative self-thoughts, creating cognitive dissonance. To relieve the tension, Jamal may realign his attitudes with his actions by viewing himself as more outgoing and confident.

Social Influence

- 5. c
- 6. a
- 7. The presence of a large audience generates arousal and strengthens Dr. Huang's most likely response: enhanced performance on a task he has mastered (teaching music history) and impaired performance on a task he finds difficult (statistics).
- 8. deindividuation
- 9. group polarization

Antisocial Relations

- 10. stereotypes
- 11. This reaction could occur because we tend to overgeneralize from vivid, memorable cases.
- 12. more
- 13. d
- 14. c
- 15. c
- 16. c

Prosocial Relations

- 17. mere exposure
- 18. companionate; passionate
- 19. d
- 20. c

- 21. mirror-image
- 22. superordinate

CHAPTER 14

PERSONALITY

Introduction to Personality and Psychodynamic Theories

- 1. repression
- 2. c
- 3. superego
- 4. b
- 5. anxiety
- 6. Projective
- 7. d
- 8. a
- 9. a

Humanistic Theories and Trait Theories

- 10. d
- 11. Rogers might assert that the criminal was raised in an environment lacking genuineness, acceptance (unconditional positive regard), and empathy, which inhibited psychological growth and led to a negative self-concept.
- 12. unconditional positive regard
- 13. Trait
- 14. c
- 15. b
- 16. b

Social-Cognitive Theories and the Self

- 17. a
- 18. social-cognitive
- 19. b
- 20. Yes, if that self-love is of the *secure* type. Secure self-esteem promotes a focus beyond the self and a higher quality of life. Excessive self-love may promote artificially high or defensive self-esteem, which may lead to unhappiness if negative external feedback triggers anger or aggression.
- 21. spotlight effect

CHAPTER 15

PSYCHOLOGICAL DISORDERS

Introduction to Psychological Disorders

- 1. depression

2. No. Anna's behavior is unusual, causes her distress, and may make her a few minutes late on occasion, but it does not appear to significantly disrupt her ability to function. Like most of us, Anna demonstrates some unusual behaviors that are not disabling or dysfunctional, and, thus, do not suggest a psychological disorder.
3. *Susto* is a condition marked by severe anxiety, restlessness, and fear of black magic. It is culture-specific to Latin America.
4. medical
5. c
6. Critics have expressed concerns about the negative effects of the DSM's labeling. Recent critics suggest the DSM-5 casts too wide a net on disorders, pathologizing normal behavior.
7. poverty
8. d

Anxiety Disorders, OCD, and PTSD

9. phobia
10. c
11. obsessive-compulsive
12. c

Depressive Disorders and Bipolar Disorder

13. women's; men's
14. d
15. norepinephrine; serotonin
16. social-cognitive

Schizophrenia

17. No. Schizophrenia involves the altered perceptions, emotions, and behaviors of a mind split from reality. It does not involve the rapid changes in mood or identity suggested by this comparison.
18. b
19. hallucination
20. a

Dissociative, Personality, and Eating Disorders

21. c
22. c
23. b
24. b

CHAPTER 16

THERAPY

Introduction to Therapy and the Psychological Therapies

1. a

2. Insight
3. d
4. active listening
5. c
6. counterconditioning
7. systematic desensitization
8. Behavior therapies are often the best choice for treating phobias. Viewing Rico's fear of the freeway as a learned response, a behavior therapist might help Rico learn to replace his anxious response to freeway driving with a relaxation response.
9. token economy
10. d
11. Cognitive-behavioral
12. b

Evaluating Psychotherapies

13. c
14. d
15. research evidence, clinical expertise, and knowledge of the patient
16. The placebo effect is the healing power of belief in a treatment. When patients expect a treatment to be effective, they may believe it was.

Biomedical Therapies and Preventing Psychological Disorders

17. c
18. antianxiety
19. lithium
20. b
21. d

APPENDIX A

PSYCHOLOGY AT WORK

1. c
2. Personnel; human factors
3. a
4. d
5. Focusing on specific, short-term goals, such as maintaining a regular study schedule, will be more helpful than focusing on more distant general goals, such as earning a good grade in this class.
6. transformational
7. c
8. d

Glossary

- absolute threshold** the minimum stimulus energy needed to detect a particular stimulus 50 percent of the time. (p. 231)
- accommodation** (1) in developmental psychology, adapting our current understandings (schemas) to incorporate new information. (2) in sensation and perception, the process by which the eye's lens changes shape to focus near or far objects on the retina. (p. 187, 240)
- achievement motivation** a desire for significant accomplishment; for mastery of skills or ideas; for control; and for attaining a high standard. (p. 454)
- achievement test** a test designed to assess what a person has learned. (p. 392)
- acquisition** in classical conditioning, the initial stage, when one links a neutral stimulus and an unconditioned stimulus so that the neutral stimulus begins triggering the conditioned response. In operant conditioning, the strengthening of a reinforced response. (p. 284)
- action potential** a neural impulse; a brief electrical charge that travels down an axon. (p. 54)
- active listening** empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers' client-centered therapy. (p. 661)
- acute schizophrenia** (also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age, frequently occurs in response to an emotionally traumatic event, and has extended recovery periods. (p. 641)
- adaptation-level phenomenon** our tendency to form judgments (of sounds, of lights, of income) relative to a neutral level defined by our prior experience. (p. 483)
- addiction** compulsive craving of drugs or certain behaviors (such as gambling) despite known adverse consequences. (p. 118)
- adolescence** the transition period from childhood to adulthood, extending from puberty to independence. (p. 203)
- adrenal [ah-DREEN-el] glands** a pair of endocrine glands that sit just above the kidneys and secrete hormones (epinephrine and norepinephrine) that help arouse the body in times of stress. (p. 64)
- aerobic exercise** sustained exercise that increases heart and lung fitness; may also alleviate depression and anxiety. (p. 508)
- affiliation need** the need to build relationships and to feel part of a group. (p. 448)
- aggression** any physical or verbal behavior intended to harm someone physically or emotionally. (pp. 162, 545)
- agonist** a molecule that increases a neurotransmitter's action. (p. 59)
- AIDS (acquired immune deficiency syndrome)** a life-threatening, sexually transmitted infection caused by the *human immunodeficiency virus* (HIV). AIDS depletes the immune system, leaving the person vulnerable to infections. (p. 436)
- alcohol use disorder** (popularly known as *alcoholism*) alcohol use marked by tolerance, withdrawal, and a drive to continue problematic use. (p. 120)
- algorithm** a methodical, logical rule or procedure that guarantees solving a particular problem. Contrasts with the usually speedier—but also more error-prone—use of *heuristics*. (p. 357)
- all-or-none response** a neuron's reaction of either firing (with a full-strength response) or not firing. (p. 55)
- alpha waves** the relatively slow brain waves of a relaxed, awake state. (p. 102)
- altruism** unselfish regard for the welfare of others. (p. 558)
- Alzheimer's disease** a neurocognitive disorder marked by neural plaques, often with an onset after age 80, and entailing a progressive decline in memory and other cognitive abilities. (p. 218)
- amphetamines** drugs that stimulate neural activity, causing speeded-up body functions and associated energy and mood changes. (p. 121)
- amygdala [uh-MIG-duh-la]** two lima-bean-sized neural clusters in the limbic system; linked to emotion. (p. 71)
- androgyny** displaying both traditional masculine and feminine psychological characteristics. (p. 169)
- anorexia nervosa** an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly underweight; sometimes accompanied by excessive exercise. (p. 651)
- antagonist** a molecule that inhibits or blocks a neurotransmitter's action. (p. 59)
- anterograde amnesia** an inability to form new memories. (p. 338)
- antianxiety drugs** drugs used to control anxiety and agitation. (p. 682)
- antidepressant drugs** drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors*—SSRIs.) (p. 683)
- antipsychotic drugs** drugs used to treat schizophrenia and other forms of severe thought disorder. (p. 682)
- antisocial personality disorder** a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist. (p. 649)
- anxiety disorders** psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. (p. 620)
- aphasia** impairment of language, usually caused by left hemisphere damage either to Broca's area (impairing speaking) or to Wernicke's area (impairing understanding). (p. 376)
- applied research** scientific study that aims to solve practical problems. (p. 12)
- aptitude test** a test designed to predict a person's future performance; *aptitude* is the capacity to learn. (p. 392)
- asexual** having no sexual attraction to others. (p. 433)
- assimilation** interpreting our new experiences in terms of our existing schemas. (p. 187)
- association areas** areas of the cerebral cortex that are not involved in primary motor or sensory functions; rather, they are involved in higher mental functions such as learning, remembering, thinking, and speaking. (p. 79)
- associative learning** learning that certain events occur together. The events may be two stimuli (as in classical conditioning) or a response and its consequences (as in operant conditioning). (p. 281)

attachment an emotional tie with another person; shown in young children by their seeking closeness to the caregiver and showing distress on separation. (p. 195)

attention-deficit/hyperactivity disorder (ADHD) a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity. (p. 615)

attitude feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events. (p. 520)

attribution theory the theory that we explain someone's behavior by crediting either the situation or the person's disposition. (p. 518)

audition the sense or act of hearing. (p. 256)

autism spectrum disorder (ASD) a disorder that appears in childhood and is marked by significant deficiencies in communication and social interaction, and by rigidly fixated interests and repetitive behaviors. (p. 192)

automatic processing unconscious encoding of incidental information, such as space, time, and frequency, and of well-learned information, such as word meanings. (p. 321)

autonomic [aw-tuh-NAHM-ik] nervous system (ANS) the part of the peripheral nervous system that controls the glands and the muscles of the internal organs (such as the heart). Its sympathetic division arouses; its parasympathetic division calms. (p. 60)

availability heuristic estimating the likelihood of events based on their availability in memory; if instances come readily to mind (perhaps because of their vividness), we presume such events are common. (p. 359)

aversive conditioning a type of counterconditioning that associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol). (p. 665)

axon the neuron extension that passes messages through its branches to other neurons or to muscles or glands. (p. 53)

babbling stage beginning at about 4 months, the stage of speech development in which the infant spontaneously utters various sounds at first unrelated to the household language. (p. 372)

barbiturates drugs that depress central nervous system activity, reducing anxiety but impairing memory and judgment. (p. 120)

basal metabolic rate the body's resting rate of energy expenditure. (p. 427)

basic research pure science that aims to increase the scientific knowledge base. (p. 11)

basic trust according to Erik Erikson, a sense that the world is predictable and trustworthy; said to be formed during infancy by appropriate experiences with responsive caregivers. (p. 199)

behavior feedback effect the tendency of behavior to influence our own and others' thoughts, feelings, and actions. (p. 474)

behavior genetics the study of the relative power and limits of genetic and environmental influences on behavior. (pp. 7, 134)

behavior therapy therapy that applies learning principles to the elimination of unwanted behaviors. (p. 663)

behaviorism the view that psychology (1) should be an objective science that (2) studies behavior without reference to mental processes. Most research psychologists today agree with (1) but not with (2). (pp. 4, 282)

belief perseverance clinging to one's initial conceptions after the basis on which they were formed has been discredited. (p. 361)

binge-eating disorder significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory purging or fasting that marks bulimia nervosa. (p. 652)

binocular cues depth cues, such as retinal disparity, that depend on the use of two eyes. (p. 249)

biological perspective concerned with the links between biology and behavior. Includes psychologists working in neuroscience, behavior genetics, and evolutionary psychology. These researchers may call themselves *behavioral neuroscientists*, *neuropsychologists*, *behavior geneticists*, *physiological psychologists*, or *biopsychologists*. (p. 52)

biomedical therapy prescribed medications or procedures that act directly on the person's physiology. (p. 658)

biopsychosocial approach an integrated approach that incorporates biological, psychological, and social-cultural levels of analysis. (p. 9)

bipolar disorder a disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.) (p. 629)

blind spot the point at which the optic nerve leaves the eye, creating a "blind" spot because no receptor cells are located there. (p. 241)

blindsight a condition in which a person can respond to a visual stimulus without consciously experiencing it. (p. 94)

bottom-up processing analysis that begins with the sensory receptors and works up to the brain's integration of sensory information. (p. 230)

brainstem the oldest part and central core of the brain, beginning where the spinal cord swells as it enters the skull; the brainstem is responsible for automatic survival functions. (p. 69)

Broca's area controls language expression—an area of the frontal lobe, usually in the left hemisphere, that directs the muscle movements involved in speech. (p. 376)

bulimia nervosa an eating disorder in which a person alternates binge eating (usually of high-calorie foods) with purging (by vomiting or laxative use) or fasting. (p. 651)

bystander effect the tendency for any given bystander to be less likely to give aid if other bystanders are present. (p. 560)

Cannon-Bard theory the theory that an emotion-arousing stimulus simultaneously triggers (1) physiological responses and (2) the subjective experience of emotion. (p. 460)

case study a descriptive technique in which one individual or group is studied in depth in the hope of revealing universal principles. (p. 28)

catharsis emotional release. In psychology, the catharsis hypothesis maintains that "releasing" aggressive energy (through action or fantasy) relieves aggressive urges. (p. 477)

central nervous system (CNS) the brain and spinal cord. (p. 60)

central route persuasion occurs when interested people focus on the arguments and respond with favorable thoughts. (p. 520)

cerebellum [sehr-uh-BELL-um] the "little brain" at the rear of the brainstem; functions include processing sensory input, coordinating movement output and balance, and enabling nonverbal learning and memory. (p. 70)

cerebral [seh-REE-bruhl] cortex the intricate fabric of interconnected neural cells covering the cerebral hemispheres; the body's ultimate control and information-processing center. (p. 74)

- change blindness** failing to notice changes in the environment. (p. 98)
- chromosomes** threadlike structures made of DNA molecules that contain the genes. (p. 134)
- chronic schizophrenia** (also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As people age, psychotic episodes last longer and recovery periods shorten. (p. 641)
- chunking** organizing items into familiar, manageable units; often occurs automatically. (p. 324)
- circadian [ser-KAY-dee-an] rhythm** the biological clock; regular bodily rhythms (for example, of temperature and wakefulness) that occur on a 24-hour cycle. (p. 100)
- classical conditioning** a type of learning in which one learns to link two or more stimuli and anticipate events. (p. 282)
- client-centered therapy** a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as active listening within a genuine, accepting, empathic environment to facilitate clients' growth. (Also called *person-centered therapy*.) (p. 661)
- clinical psychology** a branch of psychology that studies, assesses, and treats people with psychological disorders. (p. 12)
- cocaine** a powerful and addictive stimulant derived from the coca plant; produces temporarily increased alertness and euphoria. (p. 123)
- cochlea [KOHK-lee-uh]** a coiled, bony, fluid-filled tube in the inner ear; sound waves traveling through the cochlear fluid trigger nerve impulses. (p. 257)
- cochlear implant** a device for converting sounds into electrical signals and stimulating the auditory nerve through electrodes threaded into the cochlea. (p. 259)
- cognition** all the mental activities associated with thinking, knowing, remembering, and communicating. (pp. 186, 356)
- cognitive-behavioral therapy (CBT)** a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior). (p. 669)
- cognitive dissonance theory** the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes. (p. 523)
- cognitive learning** the acquisition of mental information, whether by observing events, by watching others, or through language. (p. 282)
- cognitive map** a mental representation of the layout of one's environment. For example, after exploring a maze, rats act as if they have learned a cognitive map of it. (p. 305)
- cognitive neuroscience** the interdisciplinary study of the brain activity linked with cognition (including perception, thinking, memory, and language). (pp. 5, 93)
- cognitive therapy** therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions. (p. 667)
- cohort** a group of people sharing a common characteristic, such as from a given time period. (p. 400)
- collective unconscious** Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history. (p. 577)
- collectivism** giving priority to the goals of one's group (often one's extended family or work group) and defining one's identity accordingly. (p. 157)
- color constancy** perceiving familiar objects as having consistent color, even if changing illumination alters the wavelengths reflected by the objects. (p. 251)
- community psychology** a branch of psychology that studies how people interact with their social environments and how social institutions affect individuals and groups. (p. 12)
- companionate love** the deep affectionate attachment we feel for those with whom our lives are intertwined. (p. 557)
- concept** a mental grouping of similar objects, events, ideas, or people. (p. 356)
- concrete operational stage** in Piaget's theory, the stage of cognitive development (from about 7 to 11 years of age) during which children gain the mental operations that enable them to think logically about concrete events. (p. 190)
- conditioned reinforcer** a stimulus that gains its reinforcing power through its association with a primary reinforcer; also known as a *secondary reinforcer*. (p. 292)
- conditioned response (CR)** in classical conditioning, a learned response to a previously neutral (but now conditioned) stimulus (CS). (p. 284)
- conditioned stimulus (CS)** in classical conditioning, an originally irrelevant stimulus that, after association with an unconditioned stimulus (US), comes to trigger a conditioned response (CR). (p. 284)
- conduction hearing loss** less common form of hearing loss caused by damage to the mechanical system that conducts sound waves to the cochlea. (p. 257)
- cones** retinal receptor cells that are concentrated near the center of the retina and that function in daylight or in well-lit conditions. The cones detect fine detail and give rise to color sensations. (p. 241)
- confirmation bias** a tendency to search for information that supports our preconceptions and to ignore or distort contradictory evidence. (p. 357)
- conflict** a perceived incompatibility of actions, goals, or ideas. (p. 562)
- conformity** adjusting our behavior or thinking to coincide with a group standard. (p. 526)
- confounding variable** in an experiment, a factor other than the independent variable that might produce an effect. (p. 37)
- consciousness** our awareness of ourselves and our environment. (p. 92)
- conservation** the principle (which Piaget believed to be a part of concrete operational reasoning) that properties such as mass, volume, and number remain the same despite changes in the forms of objects. (p. 189)
- content validity** the extent to which a test samples the behavior that is of interest. (p. 397)
- continuous reinforcement schedule** reinforcing the desired response every time it occurs. (p. 293)
- control group** in an experiment, the group *not* exposed to the treatment; contrasts with the experimental group and serves as a comparison for evaluating the effect of the treatment. (p. 35)
- convergent thinking** narrowing the available problem solutions to determine the single best solution. (p. 366)

coping alleviating stress using emotional, cognitive, or behavioral methods. (p. 500)

coronary heart disease the clogging of the vessels that nourish the heart muscle; the leading cause of death in many developed countries. (p. 496)

corpus callosum [KOR-pus kah-LOW-sum] the large band of neural fibers connecting the two brain hemispheres and carrying messages between them. (p. 82)

correlation a measure of the extent to which two factors vary together, and thus of how well either factor predicts the other. (p. 32)

correlation coefficient a statistical index of the relationship between two things (from -1.00 to +1.00). (p. 32)

counseling psychology a branch of psychology that assists people with problems in living (often related to school, work, or marriage) and in achieving greater well-being. (p. 12)

counterconditioning behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*. (p. 663)

creativity the ability to produce new and valuable ideas. (p. 365)

critical period an optimal period early in the life of an organism when exposure to certain stimuli or experiences produces normal development. (p. 196)

critical thinking thinking that does not blindly accept arguments and conclusions. Rather, it examines assumptions, appraises the source, discerns hidden values, evaluates evidence, and assesses conclusions. (p. 24)

cross-sectional study a study in which people of different ages are compared with one another. (p. 218)

crystallized intelligence our accumulated knowledge and verbal skills; tends to increase with age. (p. 400)

culture the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next. (pp. 7, 155)

debriefing the postexperimental explanation of a study, including its purpose and any deceptions, to its participants. (p. 41)

deep processing encoding semantically, based on the meaning of the words; tends to yield the best retention. (p. 326)

defense mechanisms in psychoanalytic theory, the ego's protective methods of reducing anxiety by unconsciously distorting reality. (p. 575)

deindividuation the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity. (p. 533)

déjà vu that eerie sense that "I've experienced this before." Cues from the current situation may unconsciously trigger retrieval of an earlier experience. (p. 346)

delta waves the large, slow brain waves associated with deep sleep. (p. 102)

delusion a false belief, often of persecution or grandeur, that may accompany psychotic disorders. (p. 640)

dendrites a neuron's bushy, branching extensions that receive messages and conduct impulses toward the cell body. (p. 53)

dependent variable in an experiment, the outcome that is measured; the variable that may change when the independent variable is manipulated. (p. 37)

depressants drugs (such as alcohol, barbiturates, and opiates) that reduce neural activity and slow body functions. (p. 119)

depth perception the ability to see objects in three dimensions although the images that strike the retina are two-dimensional; allows us to judge distance. (p. 249)

developmental psychology a branch of psychology that studies physical, cognitive, and social change throughout the life span. (p. 178)

difference threshold the minimum difference between two stimuli required for detection 50 percent of the time. We experience the difference threshold as a *just noticeable difference* (or *jnd*). (p. 232)

discrimination (1) in classical conditioning, the learned ability to distinguish between a conditioned stimulus and stimuli that do not signal an unconditioned stimulus. (2) in social psychology, unjustifiable negative behavior toward a group and its members. (pp. 267, 538)

disorder of sexual development an inherited condition that involves unusual development of sex chromosomes and anatomy. (p. 167)

dissociation a split in consciousness, which allows some thoughts and behaviors to occur simultaneously with others. (p. 265)

dissociative disorders controversial, rare disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings. (p. 646)

dissociative identity disorder (DID) a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. Formerly called *multiple personality disorder*. (p. 647)

divergent thinking expanding the number of possible problem solutions; creative thinking that diverges in different directions. (p. 366)

DNA (deoxyribonucleic acid) a complex molecule containing the genetic information that makes up the chromosomes. (p. 134)

double-blind procedure an experimental procedure in which both the research participants and the research staff are ignorant (blind) about whether the research participants have received the treatment or a placebo. Commonly used in drug-evaluation studies. (p. 36)

Down syndrome a condition of mild to severe intellectual disability and associated physical disorders caused by an extra copy of chromosome 21. (p. 403)

dream a sequence of images, emotions, and thoughts passing through a sleeping person's mind. Dreams are notable for their hallucinatory imagery, discontinuities and incongruities, and for the dreamer's delusional acceptance of the content and later difficulties remembering it. (p. 112)

drive-reduction theory the idea that a physiological need creates an aroused tension state (a drive) that motivates an organism to satisfy the need. (p. 421)

DSM-5 the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders. (p. 613)

dual processing the principle that information is often simultaneously processed on separate conscious and unconscious tracks. (p. 94)

- echoic memory** a momentary sensory memory of auditory stimuli; if attention is elsewhere, sounds and words can still be recalled within 3 or 4 seconds. (p. 323)
- eclectic approach** an approach to psychotherapy that uses techniques from various forms of therapy. (p. 658)
- Ecstasy (MDMA)** a synthetic stimulant and mild hallucinogen. Produces euphoria and social intimacy, but with short-term health risks and longer-term harm to serotonin-producing neurons and to mood and cognition. (p. 124)
- effortful processing** encoding that requires attention and conscious effort. (p. 321)
- ego** the largely conscious, “executive” part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id’s desires in ways that will realistically bring pleasure rather than pain. (p. 574)
- egocentrism** in Piaget’s theory, the preoperational child’s difficulty taking another’s point of view. (p. 189)
- electroconvulsive therapy (ECT)** a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient. (p. 685)
- electroencephalogram (EEG)** an amplified recording of the waves of electrical activity sweeping across the brain’s surface. These waves are measured by electrodes placed on the scalp. (p. 67)
- embodied cognition** in psychological science, the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments. (p. 271)
- embryo** the developing human organism from about 2 weeks after fertilization through the second month. (p. 181)
- emerging adulthood** a period from about age 18 to the mid-twenties, when many in Western cultures are no longer adolescents but have not yet achieved full independence as adults. (p. 212)
- emotion** a response of the whole organism, involving (1) physiological arousal, (2) expressive behaviors, and (3) conscious experience. (p. 460)
- emotion-focused coping** attempting to alleviate stress by avoiding or ignoring a stressor and attending to emotional needs related to our stress reaction. (p. 500)
- emotional intelligence** the ability to perceive, understand, manage, and use emotions. (p. 390)
- empirically derived test** a test (such as the MMPI) developed by testing a pool of items and then selecting those that discriminate between groups. (p. 589)
- encoding** the processing of information into the memory system—for example, by extracting meaning. (p. 320)
- encoding specificity principle** the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it. (p. 335)
- endocrine [EN-duh-krin] system** the body’s “slow” chemical communication system; a set of glands that secrete hormones into the bloodstream. (p. 63)
- endorphins [en-DOR-fins]** “morphine within”—natural, opiate-like neurotransmitters linked to pain control and to pleasure. (p. 58)
- environment** every nongenetic influence, from prenatal nutrition to the people and things around us. (p. 134)
- epigenetics** the study of environmental influences on gene expression that occur without a DNA change. (pp. 143, 612)
- equity** a condition in which people receive from a relationship in proportion to what they give to it. (p. 557)
- erectile disorder** inability to develop or maintain an erection due to insufficient bloodflow to the penis. (p. 435)
- estrogens** sex hormones, such as estradiol, secreted in greater amounts by females than by males and contributing to female sex characteristics. In nonhuman female mammals, estrogen levels peak during ovulation, promoting sexual receptivity. (p. 433)
- evidence-based practice** clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences. (p. 676)
- evolutionary psychology** the study of the evolution of behavior and the mind, using principles of natural selection. (pp. 7, 144)
- experiment** a research method in which an investigator manipulates one or more factors (independent variables) to observe the effect on some behavior or mental process (the dependent variable). By *random assignment* of participants, the experimenter aims to control other relevant factors. (p. 35)
- experimental group** in an experiment, the group exposed to the treatment, that is, to one version of the independent variable. (p. 35)
- explicit memory** memory of facts and experiences that one can consciously know and “declare.” (Also called *declarative memory*.) (p. 321)
- exposure therapies** behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imagination or actual situations) to the things they fear and avoid. (p. 664)
- external locus of control** the perception that chance or outside forces beyond our personal control determine our fate. (p. 503)
- extinction** the diminishing of a conditioned response; occurs in classical conditioning when an unconditioned stimulus (US) does not follow a conditioned stimulus (CS); occurs in operant conditioning when a response is no longer reinforced. (p. 285)
- extrasensory perception (ESP)** the controversial claim that perception can occur apart from sensory input; includes telepathy, clairvoyance, and precognition. (p. 272)
- extrinsic motivation** a desire to perform a behavior to receive promised rewards or avoid threatened punishment. (p. 305)
- facial feedback effect** the tendency of facial muscle states to trigger corresponding feelings such as fear, anger, or happiness. (p. 474)
- family therapy** therapy that treats the family as a system. Views an individual’s unwanted behaviors as influenced by, or directed at, other family members. (p. 670)
- feature detectors** nerve cells in the brain that respond to specific features of the stimulus, such as shape, angle, or movement. (p. 245)
- feel-good, do-good phenomenon** people’s tendency to be helpful when already in a good mood. (p. 479)
- female orgasmic disorder** distress due to infrequently or never experiencing orgasm. (p. 435)
- fetal alcohol syndrome (FAS)** physical and cognitive abnormalities in children caused by a pregnant woman’s heavy drinking. In severe cases, signs include a small, out-of-proportion head and abnormal facial features. (p. 182)
- fetus** the developing human organism from 9 weeks after conception to birth. (p. 181)

figure-ground the organization of the visual field into objects (the *figures*) that stand out from their surroundings (the *ground*). (p. 248)

fixation according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved. (p. 575)

fixed-interval schedule in operant conditioning, a reinforcement schedule that reinforces a response only after a specified time has elapsed. (p. 294)

fixed-ratio schedule in operant conditioning, a reinforcement schedule that reinforces a response only after a specified number of responses. (p. 294)

flashbulb memory a clear memory of an emotionally significant moment or event. (p. 331)

flow a completely involved, focused state of consciousness, with diminished awareness of self and time, resulting from optimal engagement of one's skills. (p. A-1)

fluid intelligence our ability to reason speedily and abstractly; tends to decrease during late adulthood. (p. 400)

fMRI (functional MRI) a technique for revealing bloodflow and, therefore, brain activity by comparing successive MRI scans. fMRI scans show brain function as well as structure. (p. 68)

foot-in-the-door phenomenon the tendency for people who have first agreed to a small request to comply later with a larger request. (p. 521)

formal operational stage in Piaget's theory, the stage of cognitive development (normally beginning about age 12) during which people begin to think logically about abstract concepts. (p. 191)

fovea the central focal point in the retina, around which the eye's cones cluster. (p. 242)

framing the way an issue is posed; how an issue is framed can significantly affect decisions and judgments. (p. 362)

fraternal twins (dizygotic twins) develop from separate fertilized eggs. They are genetically no closer than ordinary brothers and sisters, but they share a prenatal environment. (p. 136)

free association in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing. (p. 573)

frequency the number of complete wavelengths that pass a point in a given time (for example, per second). (p. 256)

frequency theory in hearing, the theory that the rate of nerve impulses traveling up the auditory nerve matches the frequency of a tone, thus enabling us to sense its pitch. (Also called *temporal theory*.) (p. 260)

frontal lobes portion of the cerebral cortex lying just behind the forehead; involved in speaking and muscle movements and in making plans and judgments. (p. 75)

frustration-aggression principle the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression. (p. 547)

functionalism early school of thought promoted by James and influenced by Darwin; explored how mental and behavioral processes function—how they enable the organism to adapt, survive, and flourish. (p. 3)

fundamental attribution error the tendency for observers, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition. (p. 518)

gate-control theory the theory that the spinal cord contains a neurological "gate" that blocks pain signals or allows them to pass on to the brain. The "gate" is opened by the activity of pain signals traveling up small nerve fibers and is closed by activity in larger fibers or by information coming from the brain. (p. 262)

gender in psychology, the socially influenced characteristics by which people define *men* and *women*. (p. 161)

gender identity our sense of being male, female, or a combination of the two. (p. 168)

gender role a set of expected behaviors, attitudes, and traits for males or for females. (p. 167)

gender typing the acquisition of a traditional masculine or feminine role. (p. 168)

general adaptation syndrome (GAS) Selye's concept of the body's adaptive response to stress in three phases—alarm, resistance, exhaustion. (p. 491)

general intelligence (g) a general intelligence factor that, according to Spearman and others, underlies specific mental abilities and is therefore measured by every task on an intelligence test. (p. 386)

generalization the tendency, once a response has been conditioned, for stimuli similar to the conditioned stimulus to elicit similar responses. (p. 286)

generalized anxiety disorder an anxiety disorder in which a person is continually tense, apprehensive, and in a state of autonomic nervous system arousal. (p. 620)

genes the biochemical units of heredity that make up the chromosomes; segments of DNA capable of synthesizing proteins. (p. 134)

genome the complete instructions for making an organism, consisting of all the genetic material in that organism's chromosomes. (p. 135)

gestalt an organized whole. Gestalt psychologists emphasized our tendency to integrate pieces of information into meaningful wholes. (p. 247)

glial cells (glia) cells in the nervous system that support, nourish, and protect neurons; they may also play a role in learning, thinking, and memory. (p. 54)

glucose the form of sugar that circulates in the blood and provides the major source of energy for body tissues. When its level is low, we feel hunger. (p. 426)

grammar in a language, a system of rules that enables us to communicate with and understand others. In a given language, *semantics* is the set of rules for deriving meaning from sounds, and *syntax* is the set of rules for combining words into grammatically sensible sentences. (p. 371)

GRIT Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions. (p. 567)

grit in psychology, passion and perseverance in the pursuit of long-term goals. (p. 455)

grouping the perceptual tendency to organize stimuli into coherent groups. (p. 248)

group polarization the enhancement of a group's prevailing inclinations through discussion within the group. (p. 534)

group therapy therapy conducted with groups rather than individuals, permitting therapeutic benefits from group interaction. (p. 670)

groupthink the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives. (p. 535)

habituation decreasing responsiveness with repeated stimulation. As infants gain familiarity with repeated exposure to a stimulus, their interest wanes and they look away sooner. (p. 183)

hallucinations false sensory experiences, such as seeing something in the absence of an external visual stimulus. (p. 102)

hallucinogens psychedelic (“mind-manifesting”) drugs, such as LSD, that distort perceptions and evoke sensory images in the absence of sensory input. (p. 124)

health psychology a subfield of psychology that provides psychology’s contribution to behavioral medicine. (p. 492)

heritability the proportion of variation among individuals that we can attribute to genes. The heritability of a trait may vary, depending on the range of populations and environments studied. (pp. 140, 406)

heuristic a simple thinking strategy that often allows us to make judgments and solve problems efficiently; usually speedier but also more error-prone than *algorithms*. (p. 357)

hierarchy of needs Maslow’s pyramid of human needs, beginning at the base with physiological needs that must first be satisfied before higher-level safety needs and then psychological needs become active. (p. 422)

higher-order conditioning a procedure in which the conditioned stimulus in one conditioning experience is paired with a new neutral stimulus, creating a second (often weaker) conditioned stimulus. For example, an animal that has learned that a tone predicts food might then learn that a light predicts the tone and begin responding to the light alone. (Also called *second-order conditioning*.) (p. 285)

hindsight bias the tendency to believe, after learning an outcome, that one would have foreseen it. (Also known as the *I-knew-it-all-along phenomenon*.) (p. 20)

hippocampus a neural center located in the limbic system; helps process explicit memories for storage. (pp. 71, 329)

homeostasis a tendency to maintain a balanced or constant internal state; the regulation of any aspect of body chemistry, such as blood glucose, around a particular level. (p. 421)

hormones chemical messengers that are manufactured by the endocrine glands, travel through the bloodstream, and affect other tissues. (p. 63)

hue the dimension of color that is determined by the wavelength of light; what we know as the color names *blue*, *green*, and so forth. (p. 239)

human factors psychology an I/O psychology subfield that explores how people and machines interact and how machines and physical environments can be made safe and easy to use. (p. A-2)

humanistic psychology historically significant perspective that emphasized human growth potential. (p. 5)

humanistic theories view personality with a focus on the potential for healthy personal growth. (p. 583)

hypnosis a social interaction in which one person (the hypnotist) suggests to another (the subject) that certain perceptions, feelings, thoughts, or behaviors will spontaneously occur. (p. 265)

hypothalamus [hi-po-THAL-uh-muss] a neural structure lying below (*hypo*) the thalamus; it directs several maintenance activities (eating, drinking, body temperature), helps govern the endocrine system via the pituitary gland, and is linked to emotion and reward. (p. 71)

hypothesis a testable prediction, often implied by a theory. (p. 26)

iconic memory a momentary sensory memory of visual stimuli; a photographic or picture-image memory lasting no more than a few tenths of a second. (p. 323)

id a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure principle*, demanding immediate gratification. (p. 573)

identical twins (monozygotic twins) develop from a single fertilized egg that splits in two, creating two genetically identical organisms. (p. 134)

identification the process by which, according to Freud, children incorporate their parents’ values into their developing superegos. (p. 575)

identity our sense of self; according to Erikson, the adolescent’s task is to solidify a sense of self by testing and integrating various roles. (p. 209)

implicit memory retention of learned skills or classically conditioned associations independent of conscious recollection. (Also called *nondeclarative memory*.) (p. 321)

imprinting the process by which certain animals form strong attachments during early life. (p. 196)

inattention blindness failing to see visible objects when our attention is directed elsewhere. (p. 97)

incentive a positive or negative environmental stimulus that motivates behavior. (p. 421)

independent variable in an experiment, the factor that is manipulated; the variable whose effect is being studied. (p. 37)

individualism giving priority to one’s own goals over group goals and defining one’s identity in terms of personal attributes rather than group identifications. (p. 157)

industrial-organizational (I/O) psychology the application of psychological concepts and methods to optimizing human behavior in workplaces. (p. A-2)

informational social influence influence resulting from one’s willingness to accept others’ opinions about reality. (p. 527)

informed consent giving potential participants enough information about a study to enable them to choose whether they wish to participate. (p. 41)

ingroup “us”—people with whom we share a common identity. (p. 542)

ingroup bias the tendency to favor our own group. (p. 542)

inner ear the innermost part of the ear, containing the cochlea, semicircular canals, and vestibular sacs. (p. 257)

insight a sudden realization of a problem’s solution; contrasts with strategy-based solutions. (p. 357)

insight therapies a variety of therapies that aim to improve psychological functioning by increasing a person’s awareness of underlying motives and defenses. (p. 661)

insomnia recurring problems in falling or staying asleep. (p. 110)

instinct a complex behavior that is rigidly patterned throughout a species and is unlearned. (p. 420)

intellectual disability a condition of limited mental ability, indicated by an intelligence test score of 70 or below and difficulty adapting to the demands of life. (Formerly referred to as *mental retardation*.) (p. 403)

intelligence the mental potential to learn from experience, solve problems, and use knowledge to adapt to new situations. (p. 386)

intelligence quotient (IQ) defined originally as the ratio of mental age (*ma*) to chronological age (*ca*) multiplied by 100 (thus, $IQ \times ma / ca \times 100$). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100. (p. 394)

intelligence test a method for assessing an individual's mental aptitudes and comparing them with those of others, using numerical scores. (p. 392)

intensity the amount of energy in a light wave or sound wave, which influences what we perceive as brightness or loudness. Intensity is determined by the wave's amplitude (height). (p. 239)

interaction the interplay that occurs when the effect of one factor (such as environment) depends on another factor (such as heredity). (p. 142)

internal locus of control the perception that we control our own fate. (p. 503)

interneurons neurons within the brain and spinal cord; communicate internally and process information between the sensory inputs and motor outputs. (p. 60)

interpretation in psychoanalysis, the analyst's noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight. (p. 659)

intimacy in Erikson's theory, the ability to form close, loving relationships; a primary developmental task in young adulthood. (p. 210)

intrinsic motivation a desire to perform a behavior effectively for its own sake. (p. 305)

intuition an effortless, immediate, automatic feeling or thought, as contrasted with explicit, conscious reasoning. (pp. 20, 359)

iris a ring of muscle tissue that forms the colored portion of the eye around the pupil and controls the size of the pupil opening. (p. 240)

James-Lange theory the theory that our experience of emotion is our awareness of our physiological responses to emotion-arousing stimuli. (p. 460)

just-world phenomenon the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get. (p. 541)

kinesthesia [kin-ehs-THEE-zhuh] the system for sensing the position and movement of individual body parts. (p. 269)

language our spoken, written, or signed words and the ways we combine them to communicate meaning. (p. 370)

latent content according to Freud, the underlying meaning of a dream (as distinct from its manifest content). (p. 113)

latent learning learning that occurs but is not apparent until there is an incentive to demonstrate it. (p. 305)

law of effect Thorndike's principle that behaviors followed by favorable consequences become more likely, and that behaviors followed by unfavorable consequences become less likely. (p. 290)

learned helplessness the hopelessness and passive resignation an animal or human learns when unable to avoid repeated aversive events. (p. 501)

learning the process of acquiring through experience new information or behaviors. (p. 280)

lens the transparent structure behind the pupil that changes shape to help focus images on the retina. (p. 240)

lesion [LEE-zhuhn] tissue destruction. A brain lesion is a naturally or experimentally caused destruction of brain tissue. (p. 66)

levels of analysis the differing complementary views, from biological to psychological to social-cultural, for analyzing any given phenomenon. (p. 9)

limbic system neural system (including the *hippocampus*, *amygdala*, and *hypothalamus*) located below the cerebral hemispheres; associated with emotions and drives. (p. 71)

linguistic determinism Whorf's hypothesis that language determines the way we think. (p. 379)

lobotomy a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain. (p. 687)

longitudinal study research in which the same people are restudied and retested over a long period. (p. 218)

long-term memory the relatively permanent and limitless storehouse of the memory system. Includes knowledge, skills, and experiences. (p. 320)

long-term potentiation (LTP) an increase in a cell's firing potential after brief, rapid stimulation. Believed to be a neural basis for learning and memory. (p. 332)

LSD a powerful hallucinogenic drug; also known as acid (*lysergic acid diethylamide*). (p. 124)

major depressive disorder a disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure. (p. 629)

mania a hyperactive, wildly optimistic state in which dangerously poor judgment is common. (p. 629)

manifest content according to Freud, the remembered story line of a dream (as distinct from its latent, or hidden, content). (p. 113)

maturation biological growth processes that enable orderly changes in behavior, relatively uninfluenced by experience. (p. 184)

mean the arithmetic average of a distribution, obtained by adding the scores and then dividing by the number of scores. (p. 43)

median the middle score in a distribution; half the scores are above it and half are below it. (p. 43)

medical model the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed*, *treated*, and, in most cases, *cured*, often through treatment in a *hospital*. (p. 612)

medulla [muh-DUL-uh] the base of the brainstem; controls heart-beat and breathing. (p. 69)

memory the persistence of learning over time through the encoding, storage, and retrieval of information. (p. 318)

memory consolidation the neural storage of a long-term memory. (p. 330)

menarche [meh-NAR-key] the first menstrual period. (p. 166)

- menopause** the time of natural cessation of menstruation; also refers to the biological changes a woman experiences as her ability to reproduce declines. (p. 214)
- mental age** a measure of intelligence test performance devised by Binet; the chronological age that most typically corresponds to a given level of performance. Thus, a child who does as well as an average 8-year-old is said to have a mental age of 8. (p. 393)
- mental set** a tendency to approach a problem in one particular way, often a way that has been successful in the past. (p. 358)
- mere exposure effect** the phenomenon that repeated exposure to novel stimuli increases liking of them. (p. 551)
- meta-analysis** a procedure for statistically combining the results of many different research studies. (p. 675)
- methamphetamine** a powerfully addictive drug that stimulates the central nervous system, with speeded-up body functions and associated energy and mood changes; over time, appears to reduce baseline dopamine levels. (p. 123)
- middle ear** the chamber between the eardrum and cochlea containing three tiny bones (hammer, anvil, and stirrup) that concentrate the vibrations of the eardrum on the cochlea's oval window. (p. 257)
- Minnesota Multiphasic Personality Inventory (MMPI)** the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes. (p. 589)
- mirror-image perceptions** mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive. (p. 563)
- mirror neurons** frontal lobe neurons that some scientists believe fire when performing certain actions or when observing another doing so. The brain's mirroring of another's action may enable imitation and empathy. (p. 307)
- misinformation effect** when misleading information has corrupted one's memory of an event. (p. 344)
- mnemonics** [nih-MON-iks] memory aids, especially those techniques that use vivid imagery and organizational devices. (p. 325)
- mode** the most frequently occurring score(s) in a distribution. (p. 43)
- modeling** the process of observing and imitating a specific behavior. (p. 306)
- molecular behavior genetics** the study of how the structure and function of genes interact with our environment to influence behavior. (p. 142)
- molecular genetics** the subfield of biology that studies the molecular structure and function of genes. (p. 142)
- monocular cues** depth cues, such as interposition and linear perspective, available to either eye alone. (p. 250)
- mood-congruent memory** the tendency to recall experiences that are consistent with one's current good or bad mood. (p. 336)
- morpheme** in a language, the smallest unit that carries meaning; may be a word or a part of a word (such as a prefix). (p. 370)
- motivation** a need or desire that energizes and directs behavior. (p. 420)
- motor cortex** an area at the rear of the frontal lobes that controls voluntary movements. (p. 75)
- motor (efferent) neurons** neurons that carry outgoing information from the brain and spinal cord to the muscles and glands. (p. 60)
- MRI (magnetic resonance imaging)** a technique that uses magnetic fields and radio waves to produce computer-generated images of soft tissue. MRI scans show brain anatomy. (p. 67)
- mutation** a random error in gene replication that leads to a change. (p. 145)
- myelin [MY-uh-lin] sheath** a fatty tissue layer segmentally encasing the axons of some neurons; enables vastly greater transmission speed as neural impulses hop from one node to the next. (p. 53)
- narcissism** excessive self-love and self-absorption. (pp. 453, 604)
- narcolepsy** a sleep disorder characterized by uncontrollable sleep attacks. The sufferer may lapse directly into REM sleep, often at inopportune times. (p. 110)
- naturalistic observation** a descriptive technique of observing and recording behavior in naturally occurring situations without trying to manipulate and control the situation. (p. 28)
- natural selection** the principle that, among the range of inherited trait variations, those contributing to reproduction and survival will most likely be passed on to succeeding generations. (pp. 6, 144)
- nature–nurture issue** the longstanding controversy over the relative contributions that genes and experience make to the development of psychological traits and behaviors. Today's science sees traits and behaviors arising from the interaction of nature and nurture. (p. 6)
- near-death experience** an altered state of consciousness reported after a close brush with death (such as through cardiac arrest); often similar to drug-induced hallucinations. (p. 124)
- negative reinforcement** increasing behaviors by stopping or reducing negative stimuli. A negative reinforcer is any stimulus that, when *removed* after a response, strengthens the response. (*Note:* Negative reinforcement is not punishment.) (p. 292)
- nerves** bundled axons that form neural cables connecting the central nervous system with muscles, glands, and sense organs. (p. 60)
- nervous system** the body's speedy, electrochemical communication network, consisting of all the nerve cells of the peripheral and central nervous systems. (p. 60)
- neurocognitive disorders (NCDs)** acquired (not lifelong) disorders marked by cognitive deficits; often related to Alzheimer's disease, brain injury or disease, or substance abuse. In older adults neurocognitive disorders were formerly called *dementia*. (p. 218)
- neurogenesis** the formation of new neurons. (p. 82)
- neuron** a nerve cell; the basic building block of the nervous system. (p. 53)
- neurotransmitters** chemical messengers that cross the synaptic gaps between neurons. When released by the sending neuron, neurotransmitters travel across the synapse and bind to receptor sites on the receiving neuron, thereby influencing whether that neuron will generate a neural impulse. (p. 56)
- neutral stimulus (NS)** in classical conditioning, a stimulus that elicits no response before conditioning. (p. 283)
- nicotine** a stimulating and highly addictive psychoactive drug in tobacco. (p. 121)

night terrors a sleep disorder characterized by high arousal and an appearance of being terrified; unlike nightmares, night terrors occur during NREM-3 sleep, within two or three hours of falling asleep, and are seldom remembered. (p. 111)

nociceptors sensory receptors that enable the perception of pain in response to potentially harmful stimuli. (p. 262)

norm an understood rule for accepted and expected behavior. Norms prescribe “proper” behavior. (p. 156)

normal curve (*normal distribution*) a symmetrical, bell-shaped curve that describes the distribution of many types of data; most scores fall near the mean (about 68 percent fall within one standard deviation of it) and fewer and fewer near the extremes. (pp. 45, 396)

normative social influence influence resulting from a person’s desire to gain approval or avoid disapproval. (p. 527)

object permanence the awareness that things continue to exist even when not perceived. (p. 188)

observational learning learning by observing others. (p. 306)

obsessive-compulsive disorder (OCD) a disorder characterized by unwanted repetitive thoughts (obsessions), actions (compulsions), or both. (p. 622)

occipital [ahk-SIP-uh-tuhl] lobes portion of the cerebral cortex lying at the back of the head; includes areas that receive information from the visual fields. (p. 75)

Oedipus [ED-uh-puss] complex according to Freud, a boy’s sexual desires toward his mother and feelings of jealousy and hatred for the rival father. (p. 574)

one-word stage the stage in speech development, from about age 1 to 2, during which a child speaks mostly in single words. (p. 372)

operant behavior behavior that operates on the environment, producing consequences. (p. 281)

operant chamber in operant conditioning research, a chamber (also known as a *Skinner box*) containing a bar or key that an animal can manipulate to obtain a food or water reinforcer; attached devices record the animal’s rate of bar pressing or key pecking. (p. 290)

operant conditioning a type of learning in which behavior is strengthened if followed by a reinforcer or diminished if followed by a punisher. (p. 290)

operational definition a carefully worded statement of the exact procedures (operations) used in a research study. For example, *human intelligence* may be operationally defined as what an intelligence test measures. (p. 26)

opiates opium and its derivatives, such as morphine and heroin; depress neural activity, temporarily lessening pain and anxiety. (p. 120)

opponent-process theory the theory that opposing retinal processes (red-green, yellow-blue, white-black) enable color vision. For example, some cells are stimulated by green and inhibited by red; others are stimulated by red and inhibited by green. (p. 244)

optic nerve the nerve that carries neural impulses from the eye to the brain. (p. 241)

organizational psychology an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change. (p. A-2)

ostracism deliberate social exclusion of individuals or groups. (p. 450)

other-race effect the tendency to recall faces of one’s own race more accurately than faces of other races. Also called the *cross-race effect* and the *own-race bias*. (p. 544)

outgroup “them”—those perceived as different or apart from our in-group. (p. 542)

overconfidence the tendency to be more confident than correct—to overestimate the accuracy of our beliefs and judgments. (p. 361)

panic disorder an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person experiences terror and accompanying chest pain, choking, or other frightening sensations. Often followed by worry over a possible next attack. (p. 620)

parallel processing the processing of many aspects of a problem simultaneously; the brain’s natural mode of information processing for many functions. (pp. 96, 246, 320)

paraphilias sexual arousal from fantasies, behaviors, or urges involving nonhuman objects, the suffering of self or others, and/or non-consenting persons. (p. 436)

parapsychology the study of paranormal phenomena, including ESP and psychokinesis. (p. 272)

parasympathetic nervous system the division of the autonomic nervous system that calms the body, conserving its energy. (p. 61)

parietal [puh-RYE-uh-tuhl] lobes portion of the cerebral cortex lying at the top of the head and toward the rear; receives sensory input for touch and body position. (p. 75)

partial (intermittent) reinforcement schedule reinforcing a response only part of the time; results in slower acquisition of a response but much greater resistance to extinction than does continuous reinforcement. (p. 293)

passionate love an aroused state of intense positive absorption in another, usually present at the beginning of a love relationship. (p. 556)

perception the process of organizing and interpreting sensory information, enabling us to recognize meaningful objects and events. (p. 230)

perceptual adaptation in vision, the ability to adjust to an artificially displaced or even inverted visual field. (p. 254)

perceptual constancy perceiving objects as unchanging (having consistent color, brightness, shape, and size) even as illumination and retinal images change. (p. 251)

perceptual set a mental predisposition to perceive one thing and not another. (p. 235)

peripheral nervous system (PNS) the sensory and motor neurons that connect the central nervous system (CNS) to the rest of the body. (p. 60)

peripheral route persuasion occurs when people are influenced by incidental cues, such as a speaker’s attractiveness. (p. 520)

personality an individual’s characteristic pattern of thinking, feeling, and acting. (p. 572)

personality disorders inflexible and enduring behavior patterns that impair social functioning. (p. 649)

personality inventory a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits. (p. 589)

- personnel psychology** an I/O psychology subfield that focuses on employee recruitment, selection, placement, training, appraisal, and development. (p. A-2)
- PET (positron emission tomography) scan** a visual display of brain activity that detects where a radioactive form of glucose goes while the brain performs a given task. (p. 67)
- phi phenomenon** an illusion of movement created when two or more adjacent lights blink on and off in quick succession. (p. 251)
- phobia** an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation. (p. 621)
- phoneme** in a language, the smallest distinctive sound unit. (p. 370)
- pitch** a tone's experienced highness or lowness; depends on frequency. (p. 256)
- pituitary gland** the endocrine system's most influential gland. Under the influence of the hypothalamus, the pituitary regulates growth and controls other endocrine glands. (p. 64)
- placebo [pluh-SEE-bo; Latin for "I shall please"] effect** experimental results caused by expectations alone; any effect on behavior caused by the administration of an inert substance or condition, which the recipient assumes is an active agent. (p. 36)
- place theory** in hearing, the theory that links the pitch we hear with the place where the cochlea's membrane is stimulated. (p. 259)
- plasticity** the brain's ability to change, especially during childhood, by reorganizing after damage or by building new pathways based on experience. (p. 81)
- polygraph** a machine, commonly used in attempts to detect lies, that measures several of the physiological responses (such as perspiration and cardiovascular and breathing changes) accompanying emotion. (p. 467)
- population** all those in a group being studied, from which samples may be drawn. (*Note:* Except for national studies, this does *not* refer to a country's whole population.) (p. 32)
- positive psychology** the scientific study of human flourishing, with the goals of discovering and promoting strengths and virtues that help individuals and communities to thrive. (pp. 9, 479)
- positive reinforcement** increasing behaviors by presenting positive reinforcers. A positive reinforcer is any stimulus that, when *presented* after a response, strengthens the response. (p. 292)
- posthypnotic suggestion** a suggestion, made during a hypnosis session, to be carried out after the subject is no longer hypnotized; used by some clinicians to help control undesired symptoms and behaviors. (p. 265)
- posttraumatic growth** positive psychological changes as a result of struggling with extremely challenging circumstances and life crises. (p. 691)
- posttraumatic stress disorder (PTSD)** a disorder characterized by haunting memories, nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience. (p. 623)
- predictive validity** the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity*.) (p. 397)
- prejudice** an unjustifiable (and usually negative) attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action. (p. 537)
- preoperational stage** in Piaget's theory, the stage (from about 2 to about 6 or 7 years of age) during which a child learns to use language but does not yet comprehend the mental operations of concrete logic. (p. 189)
- primary reinforcer** an innately reinforcing stimulus, such as one that satisfies a biological need. (p. 292)
- primary sex characteristics** the body structures (ovaries, testes, and external genitalia) that make sexual reproduction possible. (p. 165)
- priming** the activation, often unconsciously, of certain associations, thus predisposing one's perception, memory, or response. (pp. 231, 334)
- proactive interference** the forward-acting disruptive effect of prior learning on the recall of new information. (p. 341)
- problem-focused coping** attempting to alleviate stress directly—by changing the stressor or the way we interact with that stressor. (p. 500)
- projective test** a personality test, such as the Rorschach, that provides ambiguous stimuli designed to trigger projection of one's inner dynamics. (p. 578)
- prosocial behavior** positive, constructive, helpful behavior. The opposite of antisocial behavior. (p. 310)
- prototype** a mental image or best example of a category. Matching new items to a prototype provides a quick and easy method for sorting items into categories (as when comparing feathered creatures to a prototypical bird, such as a robin). (p. 356)
- psychiatry** a branch of medicine dealing with psychological disorders; practiced by physicians who sometimes provide medical (for example, drug) treatments as well as psychological therapy. (p. 12)
- psychoactive drug** a chemical substance that alters perceptions and moods. (p. 117)
- psychoanalysis** Sigmund Freud's theory of personality that attributes thoughts and actions to unconscious motives and conflicts. (2) Freud's therapeutic technique used in treating psychological disorders. Freud believed that the patient's free associations, resistances, dreams, and transferences—and the therapist's interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight. (pp. 572, 658)
- psychodynamic theories** view personality with a focus on the unconscious and the importance of childhood experiences. (p. 572)
- psychodynamic therapy** therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to enhance self-insight. (p. 660)
- psychological disorder** a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior. (p. 610)
- psychology** the science of behavior and mental processes. (p. 5)
- psychoneuroimmunology** the study of how psychological, neural, and endocrine processes together affect the immune system and resulting health. (p. 492)
- psychopharmacology** the study of the effects of drugs on mind and behavior. (p. 682)
- psychophysics** the study of relationships between the physical characteristics of stimuli, such as their intensity, and our psychological experience of them. (p. 230)

psychosexual stages the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct erogenous zones. (p. 574)

psychosurgery surgery that removes or destroys brain tissue in an effort to change behavior. (p. 687)

psychotherapy treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. (p. 658)

puberty the period of sexual maturation, during which a person becomes capable of reproducing. (pp. 165, 204)

punishment an event that tends to *decrease* the behavior that it follows. (p. 295)

pupil the adjustable opening in the center of the eye through which light enters. (p. 240)

random assignment assigning participants to experimental and control groups by chance, thus minimizing preexisting differences between the different groups. (p. 35)

random sample a sample that fairly represents a population because each member has an equal chance of inclusion. (p. 30)

range the difference between the highest and lowest scores in a distribution. (p. 45)

recall a measure of memory in which the person must retrieve information learned earlier, as on a fill-in-the-blank test. (p. 319)

reciprocal determinism the interacting influences of behavior, internal cognition, and environment. (p. 595)

reciprocity norm an expectation that people will help, not hurt, those who have helped them. (p. 561)

recognition a measure of memory in which the person need only identify items previously learned, as on a multiple-choice test. (p. 319)

reconsolidation a process in which previously stored memories, when retrieved, are potentially altered before being stored again. (p. 343)

reflex a simple, automatic response to a sensory stimulus, such as the knee-jerk response. (p. 63)

refractory period (1) a period of inactivity after a neuron has fired. (2) a resting period after orgasm, during which a man cannot achieve another orgasm. (pp. 55, 435)

regression toward the mean the tendency for extreme or unusual scores or events to fall back (regress) toward the average. (p. 33)

reinforcement in operant conditioning, any event that *strengthens* the behavior it follows. (p. 291)

reinforcement schedule a pattern that defines how often a desired response will be reinforced. (p. 293)

relational aggression an act of aggression (physical or verbal) intended to harm a person's relationship or social standing. (p. 162)

relative deprivation the perception that one is worse off relative to those with whom one compares oneself. (p. 484)

relearning a measure of memory that assesses the amount of time saved when learning material again. (p. 319)

reliability the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternative forms of the test, or on retesting. (p. 397)

REM rebound the tendency for REM sleep to increase following REM sleep deprivation (created by repeated awakenings during REM sleep). (p. 116)

REM sleep rapid eye movement sleep; a recurring sleep stage during which vivid dreams commonly occur. Also known as *paradoxical sleep*, because the muscles are relaxed (except for minor twitches) but other body systems are active. (p. 101)

repetitive transcranial magnetic stimulation (rTMS) the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity. (p. 686)

replication repeating the essence of a research study, usually with different participants in different situations, to see whether the basic finding extends to other participants and circumstances. (p. 26)

repression in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories. (pp. 343, 575)

resilience the personal strength that helps most people cope with stress and recover from adversity and even trauma. (p. 690)

resistance in psychoanalysis, the blocking from consciousness of anxiety-laden material. (p. 659)

respondent behavior behavior that occurs as an automatic response to some stimulus. (p. 281)

reticular formation a nerve network that travels through the brainstem into the thalamus and plays an important role in controlling arousal. (p. 70)

retina the light-sensitive inner surface of the eye, containing the receptor rods and cones plus layers of neurons that begin the processing of visual information. (p. 240)

retinal disparity a binocular cue for perceiving depth: By comparing images from the retinas in the two eyes, the brain computes distance—the greater the disparity (difference) between the two images, the closer the object. (p. 249)

retrieval the process of getting information out of memory storage. (p. 320)

retroactive interference the backward-acting disruptive effect of new learning on the recall of old information. (p. 341)

retrograde amnesia an inability to retrieve information from one's past. (p. 338)

reuptake a neurotransmitter's reabsorption by the sending neuron. (p. 56)

rods retinal receptors that detect black, white, and gray; necessary for peripheral and twilight vision, when cones don't respond. (p. 241)

role a set of expectations (norms) about a social position, defining how those in the position ought to behave. (pp. 167, 523)

Rorschach inkblot test the most widely used projective test, a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people's inner feelings by analyzing their interpretations of the blots. (p. 578)

rumination compulsive fretting; *overthinking* about our problems and their causes. (p. 635)

savant syndrome a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing. (p. 387)

- scapegoat theory** the theory that prejudice offers an outlet for anger by providing someone to blame. (p. 542)
- scatterplot** a graphed cluster of dots, each of which represents the values of two variables. The slope of the points suggests the direction of the relationship between the two variables. The amount of scatter suggests the strength of the correlation (little scatter indicates high correlation). (p. 32)
- schema** a concept or framework that organizes and interprets information. (p. 187)
- schizophrenia** a psychological disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression. (p. 640)
- secondary sex characteristics** nonreproductive sexual traits, such as female breasts and hips, male voice quality, and body hair. (p. 165)
- selective attention** the focusing of conscious awareness on a particular stimulus. (p. 96)
- self** in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions. (p. 598)
- self-actualization** according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential. (p. 583)
- self-concept** all our thoughts and feelings about ourselves, in answer to the question, "Who am I?" (pp. 200, 584)
- self-control** the ability to control impulses and delay short-term gratification for greater long-term rewards. (p. 503)
- self-disclosure** the act of revealing intimate aspects of oneself to others. (p. 557)
- self-efficacy** one's sense of competence and effectiveness. (p. 599)
- self-esteem** one's feelings of high or low self-worth. (p. 599)
- self-fulfilling prophecy** a belief that leads to its own fulfillment. (p. 563)
- self-serving bias** a readiness to perceive oneself favorably. (p. 601)
- sensation** the process by which our sensory receptors and nervous system receive and represent stimulus energies from our environment. (p. 230)
- sensorimotor stage** in Piaget's theory, the stage (from birth to nearly 2 years of age) during which infants know the world mostly in terms of their sensory impressions and motor activities. (p. 188)
- sensorineural hearing loss** the most common form of hearing loss, also called *nerve deafness*; caused by damage to the cochlea's receptor cells or to the auditory nerves. (p. 257)
- sensory adaptation** diminished sensitivity as a consequence of constant stimulation. (p. 234)
- sensory (afferent) neurons** neurons that carry incoming information from the sensory receptors to the brain and spinal cord. (p. 60)
- sensory interaction** the principle that one sense may influence another, as when the smell of food influences its taste. (p. 270)
- sensory memory** the immediate, very brief recording of sensory information in the memory system. (p. 320)
- serial position effect** our tendency to recall best the last (a *recency effect*) and first (a *primacy effect*) items in a list. (p. 336)
- set point** the point at which your "weight thermostat" is supposedly set. When your body falls below this weight, increased hunger and a lowered metabolic rate may combine to restore the lost weight. (p. 427)
- sex** in psychology, the biologically influenced characteristics by which people define *males* and *females*. (p. 161)
- sexual dysfunction** a problem that consistently impairs sexual arousal or functioning. (p. 435)
- sexual orientation** an enduring sexual attraction toward members of one's own sex (homosexual orientation), the other sex (heterosexual orientation), or both sexes (bisexual orientation). (p. 440)
- sexual response cycle** the four stages of sexual responding described by Masters and Johnson—excitement, plateau, orgasm, and resolution. (p. 435)
- shallow processing** encoding on a basic level based on the structure or appearance of words. (p. 326)
- shaping** an operant conditioning procedure in which reinforcers guide behavior toward closer and closer approximations of the desired behavior. (p. 291)
- short-term memory** activated memory that holds a few items briefly, such as the seven digits of a phone number while calling, before the information is stored or forgotten. (p. 320)
- signal detection theory** a theory predicting how and when we detect the presence of a faint stimulus (*signal*) amid background stimulation (*noise*). Assumes there is no single absolute threshold and that detection depends partly on a person's experience, expectations, motivation, and alertness. (p. 231)
- sleep** periodic, natural loss of consciousness—as distinct from unconsciousness resulting from a coma, general anesthesia, or hibernation. (Adapted from Dement, 1999.) (p. 100)
- sleep apnea** a sleep disorder characterized by temporary cessations of breathing during sleep and repeated momentary awakenings. (p. 111)
- social clock** the culturally preferred timing of social events such as marriage, parenthood, and retirement. (p. 220)
- social-cognitive perspective** views behavior as influenced by the interaction between people's traits (including their thinking) and their social context. (p. 594)
- social exchange theory** the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs. (p. 561)
- social facilitation** improved performance on simple or well-learned tasks in the presence of others. (p. 532)
- social identity** the "we" aspect of our self-concept; the part of our answer to "Who am I?" that comes from our group memberships. (p. 209)
- social leadership** group-oriented leadership that builds teamwork, mediates conflict, and offers support. (p. A-12)
- social learning theory** the theory that we learn social behavior by observing and imitating and by being rewarded or punished. (p. 168)
- social loafing** the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable. (p. 533)
- social psychology** the scientific study of how we think about, influence, and relate to one another. (p. 418)
- social-responsibility norm** an expectation that people will help those needing their help. (p. 560)
- social script** culturally modeled guide for how to act in various situations. (pp. 150, 548)

social trap a situation in which the conflicting parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior. (p. 562)

somatic nervous system the division of the peripheral nervous system that controls the body's skeletal muscles. Also called the *skel-etal nervous system*. (p. 60)

somatosensory cortex area at the front of the parietal lobes that registers and processes body touch and movement sensations. (p. 78)

source amnesia attributing to the wrong source an event we have experienced, heard about, read about, or imagined. (Also called *source misattribution*.) Source amnesia, along with the misinformation effect, is at the heart of many false memories. (p. 346)

spacing effect the tendency for distributed study or practice to yield better long-term retention than is achieved through massed study or practice. (p. 325)

spermarche [sper-MAR-key] first ejaculation. (p. 166)

split brain a condition resulting from surgery that isolates the brain's two hemispheres by cutting the fibers (mainly those of the corpus callosum) connecting them. (p. 83)

spontaneous recovery the reappearance, after a pause, of an extinguished conditioned response. (p. 285)

spotlight effect overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us). (p. 598)

SQ3R a study method incorporating five steps: Survey, Question, Read, Retrieve, Review. (p. 14)

standard deviation a computed measure of how much scores vary around the mean score. (p. 45)

standardization defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group. (p. 396)

Stanford-Binet the widely used American revision (by Terman at Stanford University) of Binet's original intelligence test. (p. 394)

statistical significance a statistical statement of how likely it is that an obtained result occurred by chance. (p. 47)

stereotype a generalized (sometimes accurate but often overgeneralized) belief about a group of people. (p. 538)

stereotype threat a self-confirming concern that one will be evaluated based on a negative stereotype. (p. 414)

stimulants drugs (such as caffeine, nicotine, and the more powerful amphetamines, cocaine, Ecstasy, and methamphetamine) that excite neural activity and speed up body functions. (p. 120)

stimulus any event or situation that evokes a response. (p. 281)

storage the process of retaining encoded information over time. (p. 320)

stranger anxiety the fear of strangers that infants commonly display, beginning by about 8 months of age. (p. 195)

stress the process by which we perceive and respond to certain events, called *stressors*, that we appraise as threatening or challenging. (p. 488)

structuralism early school of thought promoted by Wundt and Titchener; used introspection to reveal the structure of the human mind. (p. 3)

structured interviews interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales. (p. A-6)

subjective well-being self-perceived happiness or satisfaction with life. Used along with measures of objective well-being (for example, physical and economic indicators) to evaluate people's quality of life. (p. 479)

subliminal below one's absolute threshold for conscious awareness. (p. 231)

substance use disorder continued substance craving and use despite significant life disruption and/or physical risk. (p. 117)

superego the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations. (p. 574)

superordinate goals shared goals that override differences among people and require their cooperation. (p. 565)

suprachiasmatic nucleus (SCN) a pair of cell clusters in the hypothalamus that controls circadian rhythm. In response to light, the SCN causes the pineal gland to adjust melatonin production, thus modifying our feelings of sleepiness. (p. 104)

survey a descriptive technique for obtaining the self-reported attitudes or behaviors of a particular group, usually by questioning a representative, *random sample* of the group. (p. 30)

sympathetic nervous system the division of the autonomic nervous system that arouses the body, mobilizing its energy. (p. 61)

synapse [SIN-aps] the junction between the axon tip of the sending neuron and the dendrite or cell body of the receiving neuron. The tiny gap at this junction is called the *synaptic gap* or *synaptic cleft*. (p. 56)

systematic desensitization a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias. (p. 664)

task leadership goal-oriented leadership that sets standards, organizes work, and focuses attention on goals. (p. A-11)

telegraphic speech early speech stage in which a child speaks like a telegram—"go car"—using mostly nouns and verbs. (p. 372)

temperament a person's characteristic emotional reactivity and intensity. (p. 140)

temporal lobes portion of the cerebral cortex lying roughly above the ears; includes the auditory areas, each receiving information primarily from the opposite ear. (p. 75)

tend and befriend under stress, people (especially women) often provide support to others (tend) and bond with and seek support from others (befriend). (p. 492)

teratogens (literally, "monster maker") agents, such as chemicals and viruses, that can reach the embryo or fetus during prenatal development and cause harm. (p. 182)

terror-management theory a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death. (p. 581)

testing effect enhanced memory after retrieving, rather than simply rereading, information. Also sometimes referred to as a *retrieval practice effect* or *test-enhanced learning*. (pp. 13, 326)

testosterone the most important of the male sex hormones. Both males and females have it, but the additional testosterone in males stimulates the growth of the male sex organs during the fetal period, and the development of the male sex characteristics during puberty. (pp. 165, 433)

thalamus [THAL-uh-muss] the brain's sensory control center, located on top of the brainstem; it directs messages to the sensory receiving areas in the cortex and transmits replies to the cerebellum and medulla. (p. 70)

THC the major active ingredient in marijuana; triggers a variety of effects, including mild hallucinations. (p. 125)

Thematic Apperception Test (TAT) a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes. (p. 578)

theory an explanation using an integrated set of principles that organizes observations and predicts behaviors or events. (p. 26)

theory of mind people's ideas about their own and others' mental states—about their feelings, perceptions, and thoughts, and the behaviors these might predict. (p. 190)

therapeutic alliance a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem. (p. 679)

threshold the level of stimulation required to trigger a neural impulse. (p. 55)

token economy an operant conditioning procedure in which people earn a token of some sort for exhibiting a desired behavior and can later exchange their tokens for various privileges or treats. (p. 666)

tolerance the diminishing effect with regular use of the same dose of a drug, requiring the user to take larger and larger doses before experiencing the drug's effect. (p. 118)

top-down processing information processing guided by higher-level mental processes, as when we construct perceptions drawing on our experience and expectations. (p. 230)

trait a characteristic pattern of behavior or a disposition to feel and act, as assessed by self-report inventories and peer reports. (p. 586)

transduction conversion of one form of energy into another. In sensation, the transforming of stimulus energies, such as sights, sounds, and smells, into neural impulses our brain can interpret. (p. 230)

transference in psychoanalysis, the patient's transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent). (p. 659)

transgender an umbrella term describing people whose gender identity or expression differs from that associated with their birth sex. (p. 169)

two-factor theory the Schachter-Singer theory that to experience emotion one must (1) be physically aroused and (2) cognitively label the arousal. (p. 461)

two-word stage beginning about age 2, the stage in speech development during which a child speaks mostly in two-word statements. (p. 372)

Type A Friedman and Rosenman's term for competitive, hard-driving, impatient, verbally aggressive, and anger-prone people. (p. 497)

Type B Friedman and Rosenman's term for easygoing, relaxed people. (p. 497)

unconditional positive regard a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients develop self-awareness and self-acceptance. (pp. 584, 662)

unconditioned response (UR) in classical conditioning, an unlearned, naturally occurring response (such as salivation) to an unconditioned stimulus (US) (such as food in the mouth). (p. 283)

unconditioned stimulus (US) in classical conditioning, a stimulus that unconditionally—naturally and automatically—triggers an unconditioned response (UR). (p. 283)

unconscious according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware. (p. 573)

validity the extent to which a test measures or predicts what it is supposed to. (See also *content validity* and *predictive validity*.) (p. 397)

variable-interval schedule in operant conditioning, a reinforcement schedule that reinforces a response at unpredictable time intervals. (p. 294)

variable-ratio schedule in operant conditioning, a reinforcement schedule that reinforces a response after an unpredictable number of responses. (p. 294)

vestibular sense the sense of body movement and position, including the sense of balance. (p. 269)

virtual reality exposure therapy an anxiety treatment that progressively exposes people to electronic simulations of their greatest fears, such as airplane flying, spiders, or public speaking. (p. 664)

visual cliff a laboratory device for testing depth perception in infants and young animals. (p. 249)

wavelength the distance from the peak of one light or sound wave to the peak of the next. Electromagnetic wavelengths vary from the short blips of cosmic rays to the long pulses of radio transmission. (p. 239)

Weber's law the principle that, to be perceived as different, two stimuli must differ by a constant minimum percentage (rather than a constant amount). (p. 233)

Wechsler Adult Intelligence Scale (WAIS) the WAIS and its companion versions for children are the most widely used intelligence tests; contain verbal and performance (nonverbal) subtests. (p. 395)

Wernicke's area controls language reception—a brain area involved in language comprehension and expression; usually in the left temporal lobe. (p. 376)

withdrawal the discomfort and distress that follow discontinuing an addictive drug or behavior. (p. 118)

working memory a newer understanding of short-term memory that focuses on conscious, active processing of incoming auditory and visual-spatial information, and of information retrieved from long-term memory. (p. 321)

X chromosome the sex chromosome found in both men and women. Females have two X chromosomes; males have one. An X chromosome from each parent produces a female child. (p. 165)

Y chromosome the sex chromosome found only in males. When paired with an X chromosome from the mother, it produces a male child. (p. 165)

Yerkes-Dodson law the principle that performance increases with arousal only up to a point, beyond which performance decreases. (p. 422)

Young-Helmholtz trichromatic (three-color) theory the theory that the retina contains three different color receptors—one most sensitive to red, one to green, one to blue—which, when stimulated in combination, can produce the perception of any color. (p. 243)

zygote the fertilized egg; it enters a 2-week period of rapid cell division and develops into an embryo. (p. 181)

Subject Index

Note: Page numbers followed by *t* indicate a table, those in **boldface** indicate a definition, and those in *italics* indicate an illustration.

Absolute thresholds, 231–232, 232
 Acceptance, in Rogers' therapy, 583
 Accommodation, in cognitive development, 187, 187
 Accommodation, in the eye, 240
 Acetylcholine, 57–58, 58*t*. *See also* Neurotransmitters
 and Alzheimer's disease, 219
 Achievement motivation, 454–455, 578
 Achievement tests, 392. *See also* Intelligence tests
 and general intelligence, 397
 Acquired Immune Deficiency Syndrome (AIDS), 436
 and stress, 495
 Acquisition, in classical conditioning, 284–285, 299*t*
 Action potentials, 54–55, 55
 and synapses, 57
 Active listening, 661–662
 Acupuncture, 58
 and pain relief, 264
 Acute schizophrenia, 641
 Adaptation
 and anger, 477
 and conditioning, 301–303
 and natural selection, 144–145
 perceptual, 254, 254–255
 sensory, 234–235, 235
 and taste preferences, 428
 Adaptation-level phenomenon, 483
 Addiction, 118
 ADHD. *See* Attention-deficit/hyperactivity disorder (ADHD)
 Adolescence, 203–204
 cognitive development in, 205–208
 physical development in, 204–205
 and smoking, 128
 social development in, 208–213
 Adoption studies. *See* Twin and adoption studies
 Adrenal glands, 64, 64
 and emotions, 464
 Adrenaline. *See* Epinephrine
 Adulthood
 cognitive development in, 217–219
 emerging, 212
 physical development in, 214–216
 social development in, 219–225
 Aerobic exercise. *See* Exercise, aerobic
 Afferent (sensory) neurons, 60
 Affiliation need, 448–454
 benefits of, 448–450
 and ostracism, 450–451
 and social networking, 451–454
 Afterimages, 244, 244
 Age, mental, 393
 Aggression, 162, 545
 biological influences on, 545–546, 550
 and media violence, 312–313, 313

 psychological and social-cultural influences on, 547–550, 550
 and self-esteem, 604
 Aging
 cognitively, 217–219
 and intelligence, 399–401
 physically, 214–216
 socially, 219–222
 and stress, 492
 Agonists, 59, 59
 Agoraphobia, 621
 AIDS. *See* Acquired Immune Deficiency Syndrome (AIDS)
 Alcohol use, 119–120, 126*t*, 127
 and aggression, 546
 and sexuality, 439
 Alcohol use disorder, 120
 and aversive conditioning, 304, 665, 665
 Alcoholics Anonymous (AA), 118, 671
 Algorithms, problem solving and, 357
 All-or-none response, 55
 Alpha waves, 102, 102
 Alternative therapies, 677–678
 Eye movement desensitization and reprocessing, 677
 Light exposure therapy, 678
 Neurostimulation, 686–687
 Altruism, 558–559
 and bystander intervention, 559–560
 norms for, 561
 Alzheimer's disease, 218–219, 219
 American Psychological Association (APA), 4
 and the death penalty, 204
 and research ethics, 40
 and subfields of psychology, B-2*t*
 Amnesia
 anterograde, 338–339
 infantile, 185–186, 330, 348
 retrograde, 338
 source, 346
 Amok, 612
 Amphetamines, 121
 Amplitude
 of light waves, 239, 240
 of sound waves, 256, 256
 Amygdala, 71, 71, 73
 and aggression, 546
 and fear, 543
 and memory storage, 331, 331–332
 and PTSD, 623
 and schizophrenia, 642
 Anal stage, in Freud's psychosexual stages, 574*t*, 575
 Analytical intelligence, 388
 Androgyny, 169
 Anger, 477–478
 as masculine emotion, 470
 Animal magnetism. *See* Hypnosis
 Animal Mind, *The* (Washburn), 4, 367
 Animals
 culture among, 368, 368–369
 homosexual behavior among, 442, 442–443
 language among, 377–379
 natural selection and adaptation, 144–145
 and research ethics, 39–40, 197
 self-awareness among, 201, 201, 369
 thinking among, 367–368
 Anorexia nervosa, 651, 651
 Anosmia, 266
 Antagonists, 59, 59
 Anterior cingulate cortex, 450, 467, 626
 Anterograde amnesia, 338–339
 Antianxiety drugs, 682–683
 Antidepressant drugs, 683, 683–684
 Antipsychotic drugs, 682
 Antisocial behavior, 311–313, 537. *See also* Prosocial behavior
 aggression, 545–550
 prejudice, 537–545
 Antisocial personality disorder, 649–651
 Anxiety disorders, 620
 and biology, 625–627
 and cognition, 625
 and conditioning, 624–625
 generalized, 620
 panic, 620–621, 621
 and phobias, 621, 622
 APA. *See* American Psychological Association (APA)
 Aphasia, 376
 Aplysia (sea slug), 280–281, 332, 332
 Appetite
 hormones, 426, 426, 431
 and sleep deprivation, 108
 Applied research, 12
 Aptitude
 and creativity, 365
 Aptitude tests, 392. *See also* Intelligence tests
 and general intelligence, 392, 392, 397
 Archetypes, 579
 Arcuate nucleus, 426
 Arousal. *See also* Emotions
 and emotions, 460–463
 optimum, 421–422
 and passionate love, 556
 Arousal valence, 476, 476
 ASD. *See* Autism spectrum disorder (ASD)
 Asexuality, 433
 and gender identity, 170
 Assimilation, 187, 187
 Association areas, 79–81
 Associative learning, 281, 290
 Ativan, 682
 Attachment, 195
 and contact, 195–196
 deprivation of, 199–201
 differences in, 197–199
 and familiarity, 196–197
 and later relationships, 199
 Attention, selective, 95–99, 96
 Attention-deficit/hyperactivity disorder (ADHD), 615
 Attitudes, 520–523
 and actions, 520, 521
 and cognitive dissonance, 523
 and foot-in-the-door phenomenon, 521–522
 and role playing, 522–523
 Attraction, 551–558
 and matchmaking, 552–553
 and physical attractiveness, 553–555
 and proximity, 551–552
 and romantic love, 556–558
 and similarity, 555–556
 Attribution error, fundamental, 518
 Attribution theory, 518–519
 Audition, 256. *See also* Hearing
 Auditory canal, 257, 258

The Story of Psychology: A Timeline (continued from inside front cover)

- 1949**— In *The Organization of Behavior: A Neuropsychological Theory*, Canadian psychologist Donald O. Hebb outlines a new and influential conceptualization of how the nervous system functions.
- 1950**— Solomon Asch publishes studies of effects of conformity on judgments of line length.
- 1951**— In *Childhood and Society*, Erik Erikson outlines his stages of psychosocial development.
- 1951**— Carl Rogers publishes *Client-Centered Therapy*.
- 1952**— The American Psychiatric Association publishes the *Diagnostic and Statistical Manual of Mental Disorders*, an influential book that will be updated periodically.
- 1953**— Eugene Aserinski and Nathaniel Kleitman describe rapid eye movements (REM) that occur during sleep.
- 1954**— Janet Taylor's Manifest Anxiety Scale appears in the *Journal of Abnormal Psychology*.
- 1954**— In *Motivation and Personality*, Abraham Maslow proposes a hierarchy of motives ranging from physiological needs to self-actualization. (Maslow later updates the hierarchy to include self-transcendence needs.)
- 1954**— James Olds and Peter Milner, McGill University neuropsychologists, describe rewarding effects of electrical stimulation of the hypothalamus in rats.
- 1954**— Gordon Allport publishes *The Nature of Prejudice*.
- 1956**— In his *Psychological Review* article titled "The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity for Processing Information," George Miller coins the term *chunk* for memory researchers.
- 1957**— Robert Sears, Eleanor Maccoby, and Harry Levin publish *Patterns of Child Rearing*.
- 1957**— Charles Ferster and B. F. Skinner publish *Schedules of Reinforcement*.
- 1958**— Harry Harlow outlines "The Nature of Love," his work on attachment in monkeys.
- 1959**— Noam Chomsky's critical review of B. F. Skinner's *Verbal Behavior* appears in the journal *Language*.
- 1959**— Eleanor Gibson and Richard Walk report their research on infants' depth perception in "The Visual Cliff."
- 1959**— Lloyd Peterson and Margaret Peterson in the *Journal of Experimental Psychology* article, "Short-Term Retention of Individual Verbal Items," highlight the importance of rehearsal in memory.
- 1959**— John Thibaut and Harold Kelley publish *The Social Psychology of Groups*.
- 1969**— In his APA presidential address, "Psychology as a Means of Promoting Human Welfare," George Miller emphasizes the importance of "giving psychology away."
- 1971**— Kenneth B. Clark becomes the first African-American president of the American Psychological Association.
- 1971**— Albert Bandura publishes *Social Learning Theory*.
- 1971**— Allan Paivio publishes *Imagery and Verbal Processes*.
- 1971**— B. F. Skinner publishes *Beyond Freedom and Dignity*.
- 1972**— Elliot Aronson publishes *The Social Animal*.
- 1972**— Fergus Craik and Robert Lockhart's "Levels of Processing: A Framework for Memory Research" appears in the *Journal of Verbal Learning and Verbal Behavior*.
- 1972**— Robert Rescorla and Allan Wagner publish their associative model of Pavlovian conditioning.
- 1972**— Under the leadership of Derald Sue and Stanley Sue, the Asian American Psychological Association is founded.
- 1973**— Ethologists Karl von Frisch, Konrad Lorenz, and Nikolaas Tinbergen receive the Nobel Prize for their research on animal behavior.
- 1974**— APA's Division 2 first publishes its journal, *Teaching of Psychology*, with Robert S. Daniel as editor.
- 1974**— Eleanor Maccoby and Carol Jacklin publish *The Psychology of Sex Differences*.
- 1975**— Biologist Edward O. Wilson's *Sociobiology* appears; it will be a controversial precursor to evolutionary psychology.
- 1976**— Sandra Wood Scarr and Richard A. Weinberg publish "IQ Test Performance of Black Children Adopted by White Families" in *American Psychologist*.
- 1978**— Psychologist Herbert A. Simon, Carnegie-Mellon University, wins a Nobel Prize for pioneering research on computer simulations of human thinking and problem solving.
- 1979**— James J. Gibson publishes *The Ecological Approach to Visual Perception*.
- 1979**— Elizabeth Loftus publishes *Eyewitness Testimony*.
- 1981**— David Hubel and Torsten Wiesel receive a Nobel Prize for research on single-cell recordings that identified feature detector cells in the visual cortex.
- 1981**— Roger Sperry receives a Nobel Prize for research on split-brain patients.
- 1981**— Paleontologist Stephen Jay Gould publishes *The Mismeasure of Man*, highlighting the debate concerning biological determination of intelligence.

1960	George Sperling publishes "The Information Available in Brief Visual Presentations."	1983	In his <i>Frames of Mind</i> , Howard Gardner outlines his theory of multiple intelligences.
1961	Georg von Békésy receives a Nobel Prize for research on the physiology of hearing.	1984	The American Psychological Association creates Division 44 (Society for the Psychological Study of Lesbian and Gay Issues).
1962	David McClelland publishes <i>The Achieving Society</i> .		Robert Sternberg proposes the triarchic theory of human intelligence in <i>Behavioral and Brain Sciences</i> .
	Jerome Kagan and Howard Moss publish <i>Birth to Maturity</i> .	1987	Elizabeth Scarborough and Laurel Furumoto publish <i>Untold Lives: The First Generation of American Women Psychologists</i> .
	Stanley Schachter and Jerome Singer publish findings that support the two-factor theory of emotion.		Fluoxetine (Prozac) is introduced as a treatment for depression.
	Albert Ellis' <i>Reason and Emotion in Psychotherapy</i> appears; it is a milestone in the development of rational-emotive therapy (RET).		Wilbert J. McKeachie, University of Michigan, receives the first APA Award for Distinguished Career Contributions to Education and Training in Psychology.
1963	Raymond B. Cattell distinguishes between <i>fluid</i> and <i>crystallized</i> intelligence.	1988	The American Psychological Society is founded. It changes its name to Association for Psychological Science in 2006.
	Stanley Milgram's "Behavioral Study of Obedience" appears in the <i>Journal of Abnormal and Social Psychology</i> .	1990	Psychiatrist Aaron Beck receives the Distinguished Scientific Award for the Applications of Psychology for advancing understanding and treatment of psychopathology, including pivotal contributions to the development of cognitive therapy.
1965	Canadian researcher Ronald Melzack and British researcher Patrick Wall propose the gate-control theory of pain.		B. F. Skinner receives APA's first Citation for Outstanding Lifetime Contributions to Psychology and presents his last public address, "Can Psychology Be a Science of Mind?" (He died a few days later at age 86.)
1966	Robert Zajonc's "Social Facilitation" is published in <i>Science</i> .	1991	Martin Seligman publishes <i>Learned Optimism</i> , which foreshadows the "positive psychology" movement.
	Nancy Bayley becomes the first woman to receive the APA's Distinguished Scientific Contribution Award.	1992	Teachers of Psychology in Secondary Schools (TOPSS) is established as part of the APA.
	Jerome Bruner and colleagues at Harvard University's Center for Cognitive Studies publish <i>Studies in Cognitive Growth</i> .		About 3,000 U.S. secondary school students take the first Advanced Placement (AP) Examination in Psychology, hoping to earn exemption from an introductory psychology course at the postsecondary level.
	William Masters and Virginia Johnson publish results of their research in <i>Human Sexual Responses</i> .	1993	Psychologist Judith Rodin is elected president of the University of Pennsylvania, becoming the first female president of an Ivy League school.
	Allen Gardner and Beatrix Gardner begin training a chimpanzee (Washoe) in American Sign Language at the University of Nevada, Reno. Washoe dies in 2007.	1996	Dorothy Cantor becomes the first president of the APA with a Psy.D. degree.
	John Garcia and Robert Koelling publish a study on taste aversion in rats.	2002	New Mexico becomes the first U.S. state to allow qualified clinical psychologists to prescribe certain drugs.
	David M. Green and John A. Swets publish <i>Signal Detection Theory and Psychophysics</i> .		Psychologist Daniel Kahneman, Princeton University, receives a Nobel Prize for research on decision making.
	Julian Rotter publishes research on locus of control.	2011	Proposed by participants at the 2008 national conference at the University of Puget Sound, the document, "Principles for Quality Undergraduate Education in Psychology," is approved as official APA policy.
1967	Ulric Neisser's <i>Cognitive Psychology</i> helps to steer psychology away from behaviorism and toward cognitive processes.	2013	U.S. President Barack Obama announces \$100 million funding for an interdisciplinary project to advance understanding of the human brain.
	Martin Seligman and Steven Maier publish the results of their research with "learned helplessness" in dogs.		
1968	Richard Atkinson and Richard Shiffrin's influential three-stage memory model appears in <i>The Psychology of Learning and Motivation</i> .		
	Neal E. Miller's article in <i>Science</i> , describing instrumental conditioning of autonomic responses, stimulates research on biofeedback.		
1969	Albert Bandura publishes <i>Principles of Behavior Modification</i> .		

Get the most out of *Psychology*, eleventh edition with  LaunchPad, which combines an interactive e-Book with high-quality multimedia content and activities that give immediate feedback. Learn more at www.launchpadworks.com.
